ON Tuesday last the members and associates of the Institution of Civil E the Institution of Civil Engineers and their friends dined together at Willis's Rooms, St. James. The president, Mr. C. H. Gregory, occupied the chair. Amongst the company, which numbered about 300, were the following:—The Duke of Buckingham, Viscount Stratford de Redeliffe, Lord Houghton, Lord Lawrence, Lord W. Lennox, Lord Alfred Churchill, Viscount Bury, M.P., Lord Richard Grosvenor, M.P., the First Lord of the Admiralty, Field Marshal Sir John Burgoyne, General the Hon. James Lindsay, Baron Bramwell, the Astronomer Royal, Professor Owen, the Presidents of the Royal Academy, Astronomical and Chemical Societies, and Institute of British Architects, &c. The Duke of Buckingham, in giving "Prosperity to the Institution of Civil Engineers," coupled with it the name of the senior past president present, Mr. Bidder, paid a high though deserved tribute to the value of the services of the civil engineers. They had promoted trade and commerce everywhere, and had done more to advance the happiness, prosperity, and convenience of mankind than any other body of men that ever lived. Mr. Bidder briefly returned thanks. Amongst the other speakers during the evening were Lord Stratford de Redeliffe, Lord Lawrence, Lord Houghton, Baron Bramwell, Lord Bury, &c.

THE funeral of Sir Edward Cunard was solemnized at New York, on the 10th inst., and his remains were laid in Trinity churchyard, New York city, by the

# ALPHABETIC TELEGRAPH. MAGNETO-ELECTRIC BY M. BREGUET.

Frg. 1.

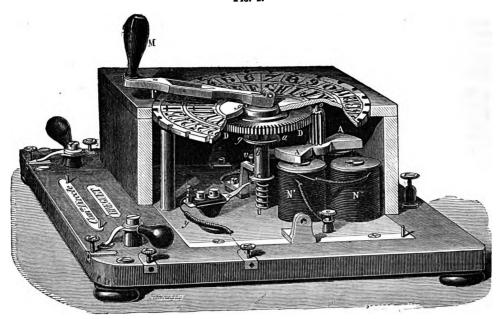

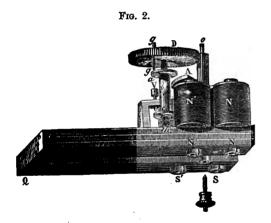

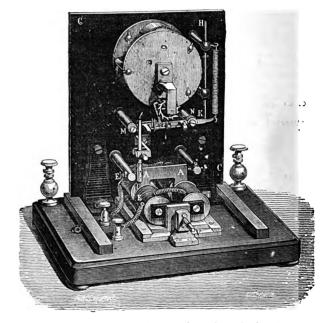

Fig. 3.

## MAGNETO-ELECTRIC ALPHABETIC TELEGRAPH.

THIS instrument will, at the first glance at our Hills instrument will, at the first glance at our illustrations, strike the observer as being similar to Brequet's ordinary alphabetic telegraph; but a little closer studying will show that the source employed for working the instrument is, in the present case, magneto-electricity, whilst, in Brequet's ordinary telegraph, voltaic electricity is used as the electro-motor. This instrument was arbitisted at the Davis Tabilities returned to writed used as the electro-motor. This instrument was exhibited at the Paris Exhibition, where it excited some attention. It is known as "Guillot's system," but the general arrangement and details are mostly the same as in Berguet's, the favourite French railway instrument. The system consists of two parts, the "manipulator" or sending key, and the "receiver" or alphabetic dial. The sending key is very easy for manipulation, owing to the simplicity of its mechanism and to the peculiar fea-tures which it presents. Fig. 1 of our engraving shows a general view of the manipulator. Fig. 2 shows a general view of the manipulator. Fig. 2 shows the peculiar arrangement of magnets and armatures. In the pedestal of the instrument is fixed a permanent magnet, consisting of three superposed magnets screwed together, fig. 2. Upon the extremities of the poles of the magnet are placed cylindrical cores of soft iron, carrying four wooden bobbins wound with insulated wire. These contents of a second content of the cont

true square. An armature A A turns on its centre o, which, at the same time, is the centre of the square. So situated, the soft iron cores become magnetized, and each time that the armature passos from one diagonal to another of the square, currents are produced in the four bobbins. Two of these currents are produced by the removal of the armature from the "core;" and the other two by its approach. The first are much stronger than its approach. The first are much stronger than the second currents, but the sum of the whole four is always equal, and this sum is obtained by conveniently uniting the extremities of the wires of the four bobbins so as to form only one circuit. When the armature passes from a diagonal position N S 1 to another N 1 S 1, the current produced is in one direction or sign. When the armature continues its movement and passes to the position S¹N, a second current is produced of the contrary sign to the first, because the first current was due to the "removal" of the armature from the bobbins N and S¹, and of "approach" to those of S and N¹; whilst, in the second case, the opposite positions would be the case; or, in other words, the two removals of the armature in one position correspond to the two approaches in the other.

The movement of the armature is obtained by means of a pinion of 20 teeth geared into a wheel of 120 teeth, D, on the axis of which is fixed the

of a revolution; so that, when the handle passes from one letter A to the succeeding one B, a current is sent of one sign. When the handle passes to the next letter from B to C, a second current is to the next letter from B to C, a second current is sent of the opposite sign, so that, by the present key, a current is sent for every letter; for one half the currents will be of one sign, and for the other half of the opposite sign. The manipulation of the key is not interfered with by the peculiar magnetic attractions and repulsions that take place between the armature and the four bobbins; and from experience it is found that very little more force is required to keep turning the handle than

in the ordinary manipulator.

The arrangement in the key for sending and recoiving are somewhat novel, and very simple. So long as the handle is raised, as in the position in fig. 2, so long is the communication established between the line and the bobbins, and by turning the handle, the currents induced are sent entirely into the line without the possibility of any loss. When the handle is depressed by dropping the pin under the handle into any one of the notches on the outer circumference of the manipulator, the com-munication between the line and the bobbins is broken, and the line is thrown into connection with the receiving instrument, and each time that this is done, the sender can be interrupted by his correwooden bobbins wound with insulated wire. These cores N N 1 S S 1 are placed at the four angles of a 1-26th of a revolution, the armature makes 1-4th place in whatever position the depressed sending

key may be. The object of this disposition is to prevent the loss of any part of the current, in consequence of the fault of any of the current, in consequence of the fault of any of the contacts, &c. This result is obtained by means of a commutator carried in the axis of the manipulator, and capable of an upward and downward movement between two fixed circuits. This cylinder or bobbin ab c communicates with the mass of the apparatus and with the line; when it is in its lower position, it presses against the spring U, which communicates with the receiving instrument; when in its upper position, the spring U forces it up against the screw v, which communicates with the bobbins of the manipulator, so that in this position, currents are sent direct into the line. The commutator ab c is maintained against the screw by the spring U, but, on the other hand, it is pressed downwards by a pin g passing through the axis which is pressed against the upper surface of a by means of the handle M. So that it will be seen in ordinary sending, on turning the handle round, a current will be induced, and sent into the line for each letter. When it is required to signal any letter, the handle is dropped into the notch corresponding to the latter, and in this position, the line is commutated to the receiving instrument; the weight of the handle is sufficient to maintain the commutator in its lower position. On lifting up the handle, the bobbins are once more in communication with the

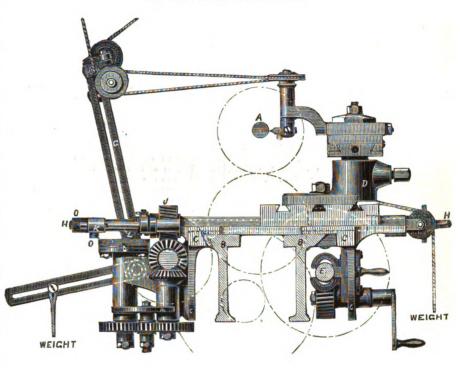

For working with this manipulator, a difference in the receiving instrument was necessary. In the ordinary alphabetic instruments they received with a current of only one sign, but the present key transmits currents of alternate signs, and it was necessary to have a needle advancing a letter for each current sent, no matter the sign. Fig. 3 shows a magnetized horse-shoe armature A A placed between two electro-magnets E E !, which are placed so as to have their opposite poles to each other, so that when a current passes through E, the armature is attracted by it, and repelled by E !. A current of an opposite sign will produce contrary results. Every current, therefore, will effect a movement in the armature, first in one direction, then in the other; the armature being without a spring, remains always in the last position when attracted: it remains so until a current of an opposite nature is passed. Each time a current is sent from the manipulator, the armature is attracted, and the motion is communicated to a detent, which allows the escapement wheel to advance one step, and, consequently, the needle to advance from one letter on the dial to the succeeding. This receiving instrument never requires regulating, because the two successive movements are always equal; it is sufficient that the current received should always possess an intensity superior to a certain minimum, so that the working of the instrument will be certain. These instruments are manufactured by MM. Buguet, of Paris, and have now been at work on some lines in France for some time, and they have given every satisfaction.

# SLIDE REST FOR TURNING IRREGULAR SECTIONS.

In our impression for August 14 last year we reviewed a very useful work upon "Lathes and Turning," by Mr. W. H. Northcott. The author of that book has since worked out a highly ingenious piece of mechanism for turning irregular forms, which we illustrate herewith. This system differs from the Blanshard and other lathes, inasmuch as it is applicable to ordinary slide and screw cutting purposes in addition to its capability of turning irregular forms. A is the centre line of lathe spindle, B is the lathe bed which carries a pair of ordinary headstocks, C is the saddle of the slide rest caused to travel along the bed by means of the leading screw E, D is a rest holder bolted to the surfacing slide, and is shown carrying an ordinary short slide with Willis's holder and a light fly cutter. This or other cutter is driven from overhead by means of a cord or gut which is kept strained in every position of the slide by means of the lever G. The shaft F and the leading screw E are driven from the lathe spindle by suitable change wheels, but generally the shaft F has to run at the same speed as the lathe spindle. The surfacing slide carrying D is caused to move across the saddle by means of the screw H, either by a handle in front or automatically by the worm wheel I driven from a worm on the shaft F, the motion of the screw by means of a sliding clutch. The surfacing screw H is continued past the worm wheel and clutch, and at its end is fitted with bearing and

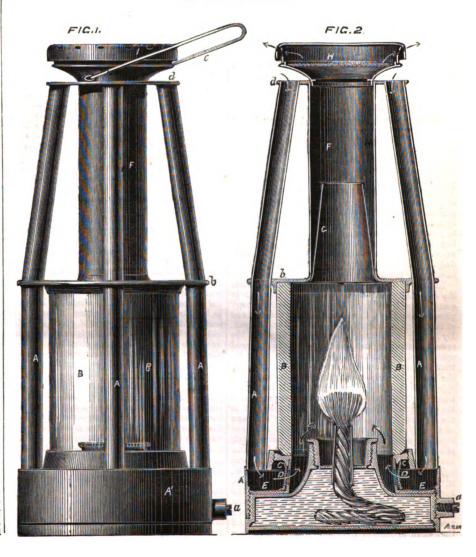

# IMPROVED SLIDE REST.

BY MR. W. H. NORTHCOTT.

# SAFETY MINER'S LAMP.

BY MR. T. GRAY.

adjusting nuts for running in the crosshead K, which crosshead slides on guides L, one each side of the traverse screw.

The shaft F carries a small wrought-iron mitre wheel which rotates with the shaft, but by sliding along it is enabled to follow the saddle anywhere on the bed. This mitre wheel gears with a similar mitre wheel below it, attached to a short vertical spindle, having its bearings in a casting fastened to the saddle. At the lower end of this spindle is a spur wheel, one of a series of changes, any of which may be used to obtain the required There is also another longer vertical speeds. spindle which rotates in a boss forming part of the same frame. This spindle also takes a change wheel, which is driven either directly from the wheel on the other spindle, or through intermethe long spindle has a large collar or disc, to which is fastened another disc. is fastened another disc or receiving plate N. The fastening is made by two bolts with T heads fitting into a circular dovetail groove in the top plate, and passing through the collar below. of one plate is graduated, and the other is furnished with a pointer, so the top plate may be moved round any distance, and then fastened by tightening the nuts below. The top plate has a number of screwed holes to allow of fastening various shaper plates to it. The sliding crosshead K carries a suitable rubber O placed just below the bearing of the screw H, and the shape of this rubber depends upon the shape of the copy plate. The surface screw H has its usual bearings in the metal of the saddle, but the collars to the front bearing are formed by four nuts (shown dotted) which allow of any end play being taken up. The inside pair of nuts, however, must be screwed back when the irregular turning mechanism is in use. as the screw H has to slide lengthwise through its bearings.

On the lathe being started, the mitre wheel drives the short vertical spindle, and this motion is communicated by the change wheels to the copy plate attached to the top of the second verti-The shaper plate, in rotating, being pressed against by the rubber O, causes the cross head K and screw H to reciprocate, or slide end-ways in its bearings, and this motion is of course partaken of by the slide and tools carried by the slide. The rubber is kept in contact with the copy plate by a weight attached to the slide, and passing over a small pulley in front, so that the surfacing slide may still be moved by turning its screw, and the pressure upon the copy plate is not affected by the position or movement of the slide. When using the mechanism, the surfacing slide should be well oiled and made to slide freely, as then less weight will suffice to keep the rubber against the copy. The shape of the copy plate is against the copy. not difficult to determine, as any copy will either produce its counterpart or its inverted profile according to the position of the tool's point relative to the centre of the work. The best plan for ascertaining the shape of the plates is by means of a diagram. With an eccentric circle for the copy plate, a variety of forms can be produced. The eccentric will produce an eccentric with the tool's point either side of the lathe centre, but a slight alteration of its position will alter the figure. Whatever figure the copy has been shaped to produce on a surface, it is obvious that, by moving the tool along the lathe bed in the usual manner, a long shaft of the same section is pro-duced, and the shaft can be made to taper just as in ordinary turning.

In most of these applications of the mechanism, the copy and work make equal rotations, but, in some cases, it is more convenient for the copy plate to rotate two, three, four or more times to one of the work, as a simpler copy may then be used. By having a very slight difference between the speeds of the copy and work, the work is rendered spiral, that is, whatever shape its section may be, that shape continually changes its position. If the copy plate rotates faster than the work, the spiral is left-handed; if slower, it will be righthanded. The pitch of the spiral will depend upon the relative speeds of copy, work, and tool, and is the distance travelled by the tool during one turn of the spiral. These spiral forms are rendered tapering in the usual manner, and secondary spirals of any pitch can be cut upon them. The irregular shape mechanism is very usefully applied to turning cams, the cutting tools depending, of course, upon the shape to be produced; but, as a rule, revolving cutters are to be preferred, as the lathe may then be driven slowly. Curved slots and

only have to be turned, the work and copy plate generally make equal rotations, and, when the position of the section has to vary, there must be some slight difference between their speeds. giving the copy a very slow motion compared with the work, instead of the article having an irregular transverse section, it is turned circular, but of irregular longitudinal section. For instance, by having a copy plate formed of a true spiral, tapering shafts are produced. Having an eccentric circle for the copy, and rotating it very slowly compared with the work, the work is circular in section, and is formed longitudinally of a series of alternating internal and external curves. shape is produced automatically, and may be rendered tapering; or a spiral of any pitch may be cut upon it just as easily as upon a cylinder.

The practical applications of Mr. Northcott's mechanism are both useful and various. The curves of connecting rods are very readily produced by an eccentric circle copy plate. curved faces of belt pulleys can also be produced and given to one or to any number on shaft by the repeated rotations of a small eccentric plate. The drawing rollers of spinning machinery, handles of starting levers, bolts with countersunk heads, and many other articles frequently required in large numbers, can also be produced from suitably formed copy-plates; whilst, for cabinet making and for ornamental turning, the applications of the mechanism are almost endless.

### GRAY'S SAFETY MINER'S LAMP.

THE recent deplorable accidents in mines would A appear to have stimulated the inventive talent of the country to further attempts to produce a miner's lamp, which should really deserve the title of "safety." We recently noticed one invention for this purpose, and we now place before our readers another, which equally merits the attention of those who are interested in preventing these fatal catastrophes. It is the patented invention of Mr. Thomas Gray, mining engineer, of Taibach, Glamorgan, and in it the "poles," which in other safety lamps support and keep together the different parts, are hollow, for the purpose of supplying the flame with the necessary oxygen to support combustion. These hollow or tubular poles connect the extreme top and bottom of the lamp; at the bottom they are screwed into a chamber, in which the air, after passing down the poles, circulates, and in which there is a ring of wire gauze, through which the air passes to the flame. From the flame the heated air and products of combustion ascend the ordinary glass cylinder and a metal chimney placed in the wire gauze cylinder. The wire gauze ring prevents the return up the hollow poles of the ignited gas, while the lamp is surrounded by, or is being used to detect the presence of, inflammable gas. A cap prevents dust entering the top of the hollow poles.

Fig. 1 of the accompanying engraving is an elevation of a safety lamp fitted with Mr. Gray's improvements, and fig. 2 is a sectional elevation of the same. A A are the hollow poles, secured at the bottom to the upper part of the gallery A 1 of the lamp. This portion of the gallery forms an air-distributing chamber, by which the air which passes down the hollow poles becomes equally distributed over the whole area of the chamber. D is the vertical ring of wire gauze, through which the air passes to the flame, dicated by the arrows, and which prevents any ignited mixture of gas from communicating with the explosive atmosphere in which the lamp may This ring D of wire gauze is sustained in be. position by a washer E, part of which is vertical, and part bears on its outside edge a screw thread. by which it is screwed to the chamber. The ver-tical part has apertures for the passage of air at intervals. A part of this washer E, marked C, screws up into a projecting flange of the chamber or gallery, and retains the glass cylinder B in its place. This part, C, of the washer, has on its place. under side a projection, which serves as a guide for the washer E, when being screwed, and keeps the wire gauze ring in its place. These two washers, therefore, when screwed into place, are combined, and support the vertical ring of wire gauze, and all the air which the flame requires must pass through it.

The body or oil reservoir of the lamp is screwed up into the lower portion of the gallery, and is firmly held in place by a tightening screw a. The flange O supports the glass cylinder B. The glass apertures, through which the hollow poles pass, and by which they are held in place and steadied. The upper end of the chimney is spread out, and carries a wire gauze disc H, through which the products of combustion pass. Over this disc gauze is placed a cap, made with apertures for the passage of the heated air and smoke, and in such that when the lamp is in any current of air, the flame burns uniformly and is not affected thereby. The tops of the hollow poles are attached to a flange d, to which the handle or loop e, by which the lamp is carried, is fastened.

Mr. Gray sometimes fits into the neck of the

a cone or tapered tube G, by which the draft of air supplied to the flame is governed. A cap can be placed over the tops of the poles when necessary to prevent dust entering them.

The advantages of this lamp are that it will not burn in an explosive mixture of gas and air, the quantity of air in consequence of sufficient to support combustion, so that when the lamp is placed in gas it is brought down the air the exclusion of the necessary quantity of air, and the light is extinguished. It will not, when exposed to currents of explosive mixtures, By the air being admitted at the flame. top of the lamp, the smallest quantity of gas which may be near the roof of the mine is detected, by being brought down the air tubes into direct contact with the flame. By the small quantity of gauze used, the danger of the lamp being injured by the workmen's tools, or falling stones or coals, is much lessened.

COMPARISON BETWEEN THE WHITWORTH POLYGONAL AND THE WOOLWICH STUDDED PROJECTILES.

BY MR. JOSEPH WHITWORTH, C.E., F.R.S., &c.

UNDER the above heading we have a very U suggestive paper from the pen of Mr. Whitworth, and one which will be perused with interest by all our readers. In this paper Whitworth projectiles cast with rifled polygonal surfaces are compared with Woolwich projectiles, with dove-tailed recesses for the insertion of soft metal studs to give rotation. The subject is treated under three heads:—1. Simplicity and economy of production. 2. Area of bearing sur-3. Centring of the shot in the bore of the faces.

## 1. SIMPLICITY AND ECONOMY OF PRODUCTION.

Polygonal.-Projectiles for field guns are fired as they are cast, just as in the case of smooth bores. For large guns, they are planed or shaped, one machine only being required. The time occupied in rifling a 9-inch shell, weighing 300lb., is only twelve minutes. In studded projectiles the body of the shot has to be cast with recesses for the studs, or they have to be drilled in, and recessed with cutters. In either case these recesses are a source of weakness, rendering the shell liable to break up in the bore of the gun. The 9-inch projectile has 12 stude inserted in it, by pressure, each one requiring attention; there are also six different surfaces to attend to, viz:—The body of the shot, the outer circumferences of the studs, the right and left sides of the rear studs, and the right and left sides of the front studs, which are made narrower than the rear studs, on account of the increasing pitch. The projectile for field guns has six brass studs fitted into it.

Studded projectiles have in their manufacture to pass through several workmen's hands, and costly machines have to be employed, viz:-lathes or grinding machines, drilling and punching machines, in addition to the rifling The cost of wages for the large projectiles is many times greater than for those of the polygonal system; the cost of the metal for stude is considerable; and to this must be added the cost of a packing case or thick canvas bag for each projectile, on account of the soft metal studs being liable to injury if one projectile is allowed to rest upon or knock against another. In the penetration of armour plates the stude are an obstruction, and the power required to shear them off is so much deducted from the force of the projectile.

# 2. AREA OF BEARING SURFACES.

For a 9-inch polygonal projectile, the rifled surfaces which both support and rotate the shot have an area of 187in. The 12 stude of a 9-inch Palliser projectile have a circumferential area of 18in. for supporting the shot, but the area of the grooves are also easily and automatically cut by means of this mechanism. It will be understood that when articles of irregular transverse section metal chimney F. This flange is provided with motion is given, is only 1-6inch. No practical

engineer would think of providing so small a surface to give even a small amount of rotation to a body weighing 250lb., much less when the rotation of the shot at the muzzle of the gun has to be at the rate of about 2,400 revolutions per minute. The increasing pitch which has been adopted prevents the use of more than one stud in each groove for giving rotation. This varying curve is groove for giving rotation. This varying curve is the worst possible mode of imparting rotation, for each rear stud can only bear against the side of the groove of the gun on a line of its surface, on account of the ever varying curve, except by excessive pressure, which jams and distorts the soft metal, and occasions liability to accident. The greater the amount of windage, the greater will be the liability to accident.

# 3. CENTRING OF THE SHOT IN THE BORE.

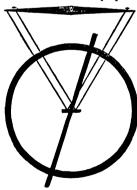

In starting, the polygonal projectile centres itself, so that its axis coincides with the axis of the gun, and it is propelled through the bore with a steady equable motion. The studded projectile in starting does not rise and centre itself parallel with the axis of the bore, but lies on the bottom; consequently, the gases and unconsumed powder pass sequently, the gases and unconsumed powder pass over the projectile, causing excessive scoring, and tending to keep the shot down, thus giving increased pressure to the outer surfaces of the stude, particularly those of the rear, and adding to the irregular and vibratory motion as it is propelled through the bore, and the greater the windage, the more unsteady will be the motion.

Following the foregoing is a short paper, by the same author, on the proof of guns, which we reserve for next week.

reserve for next week.

### THE DIP CIRCLE.

A T a recent meeting of the Manchester Literary and Philosophical Society Dr. Jones F.P.S. A and Philosophical Society, Dr. Joule, F.R.S., gave an account of his endeavours to improve the instrument known as the dip circle, which, notwithstanding what had been done by Lloyd and others, was not comparable in delicacy to the decli-The ordinary mode of causing the axis of the needle to roll on agate planes first claimed attention. He found it possible to obtain a steel cylinder of beautiful accuracy as follows :- A steel wire, stretched by a weight hanging from one ex-tremity, being heated to redness, draws out a cer-tain length, and in so doing becomes perfectly straight. The wire is then divided into pieces each about 2in. long, which are ground true and then polished by rolling them against one another. If the operation has been carefully conducted, one one wire laid across two others will roll noiselessly down an almost imperceptible gradient. The plan of suspension thus indicated appeared better than the use of agate planes, inasmuch as dust and moisture were less likely to interfere with the delicacy of the indications. Nevertheless, it was impossible attogether to avoid the effects of these impediments to free rotation, and the more so as the obstruction to rotation is proportional to the

square root of the height of any small particle between the rolling surfaces. In fact, on narrowly watching the periods of oscillation, they were invariably found to become sensibly quicker when the arc was very small, showing that the needle was rocking on two points. The suspension by inclined silk threads was then tried, but soon abandoned, as it was found that the violent torsion at the points of attachment could not be certainly

allowed for, owing to the viscosity of the threads.

The system brought now before the Society was The system brought now before the Society was free from the above-named evils. It is illustrated in the accompanying sketch. In it each end of the axis of the needle is suspended by a fibre of silk, on which it rolls. Small washers on the axis serve to keep the fibres in a definite position. The ends of the fibres are supported by the extremities

of a delicate balance beam, placed at the top of the instrument. Small pins, &c., are used for adjusting the length of the fibres and to regulate the centre of gravity of the beam. The needle itself is a piece of softened watch main spring, sufficiently long to extend completely across the graduated circle. It is 7in. long and weighs eighteen grains. A glass plate fastens before the instrument by a notch. By the reflection of the eye of the observer from this glass parallax is avoided, while the position of each edge of the needle is read off by an eye-glass to a minute of arc. There is no difficulty in adapting the reflecting system for the purpose of registering minute magnetic disturbances.

### THE DURABLE COMPOSITION INKING ROLLER.

T is a matter of the first importance with printers that they should always find their inking rollers in a proper condition to do good work. This the ordinary glue and molasses rollers very rarely are; besides which, they have a tendency to dry, shrink, and crack, after a short term of working, requiring constant attention and renewal. A material, therefore, which does not require continued looking after, which remains moist, and which, moreover can be recast in case of injury to its surface, will prove a boon to the printing trade. Such a composition has long been sought for, and now appears to have been found in the patent inking rollers of Messrs. Lawrence Brothers, of 22, Basinghall-street, London. This composition is a mixture of glue, glycerine, sugar, and other saccharine matters, soap, and fixed oils, in combination and proportions variable according to temperature, climate, and destined uses. About three months since, we received one of these composition rollers from Messres. Lawrence, and at once handed it over to our printers to make the best and worst use they could On enquiring, the other day, we found the roller to be in just as good condition as it was on the day it was first used. There was no shrinkage, cracking, nor hardening in the cold mornings, nor any other inconvenience incidental to the ordinary printing rollers. On the other hand, we find that the composition roller never loses suction, does not require washing at the end of the day's work, is not affected by heat, and is, in fact, as perfect a printing roller as could be wished. The success of this roller in our hands shows it to be a composition which must rapidly find favour with the printing fraternity wherever it is known.

# GAS IN SINGAPORE.

THE annual general meeting of the Singapore Gas Company was held last Tuesday, and the report of the directors then presented, show a profit of £1,267 for the half-year. From the engineer's report, we learn that Labuan and Australian coals work well togother. For the half-year—gas produced 2,090 cubic feet per ton; gas paid for 8,220 cubic feet; lost or deficiency, including the consumption on the works, 92 per cent. The oxide of iron and ammoniacal liquor process for purifying continues to work well without the of lime, and the original oxide is still at k. The new Government House is ordered aid work. work. The new Government House is ordered to be lighted, and an estimate has also been sent in for the lighting of the General Hospital; should this be carried out, three public lamps in addition will be placed on that line of road. For the supply to Government House, a main will have to be taken from Selegie-road, across the Princeps Estate, which will give the Europeans in that vicinity an opportunity of taking gas. One house is fitted up and another ordered. The main laying has been commenced. We are glad to observe that the prospects of this enterprise continue to be encouraging.

# THE CHANNEL BRIDGE.

THE CHANNEL BRIDGE.

THE following is a translation of a paragraph in the "Journal Officiel del'Empire Francais" of the 16th inst:—"The project of a bridge over the straits makes each day further progress. The first model was completely finished some days ago, and is perfectly satisfactory. This small model is composed of a single arch, reduced upon an exact scale to the hundredth part of the size of one of those of the great bridge. It presents an absolute rigidity thoughout, that is to say, it is not subject to any movement or oscillation; there is, consequently, no vibration calculated to disintegrate the metal. There is no more elasticity perceptible under foot than in walking on a pavement, and it can support without any defice-

tion, a weight greater than twenty trains proportioned to the same scale, meeting in the middle of the arch. The weight of ten men does not produce a deflection of more than a few millimetres in its whole length, and as soon as it is relieved of its burden, it recovers exactly its first position—indeed, it was not necessary to employ several of the parts prepared to insure rigidity. This result simplifies the question, and permits considerable economy in the cost. A second model of a size double that of the first is on the point of being completed, and, if, as everything tends to show, the result is as favourable, the most sceptical will be unable to entertain the smallest doubt in respect of it. In any case, the problem is resolved that bridges and viaducts of every size can be constructed in a single arch without piers from bank to bank. Already, many orders for large and small bridges have been given; among others, a large bridge with a road and railway of a kilometre in length, which will unite St. Male and St. Servan to Dinard, a foot bridge of 100 metres over the basin of the loch at Calais, and several others for the departments." at Calais, and several others for the departments.

# ON VENTILATION. By Dr. Edward Smith, F.R.S.

PART III.-CONCLUSIONS. (Concluded from page 281.)

T now remains for me to state summarily the con-

Thow remains for me to state summarily the conclusions to which a consideration of the subject
and my official experience have led me.

1. Interchange of air which proceeds both by
diffusion and removal is not instantaneous. The
rapidity of interchange varies with many circumstances.

stances.

2. The effects of any natural system of ventilation vary with the season as well as with the special conditions of a building and the number of inmates.

3. There is a relation between ventilation and temperature, which in reference to inhabited rooms

is generally an inverse one, and as the human body requires a temperature of the air of from 55deg. to

requires a temperature of the air of from 55deg. to 65deg. according to the season, ventilation in cold weather must be restricted by the lower, and in hot weather by the higher temperature.

4. The movement of the air, although so essential to health, must not be very perceptible, lest it should cause discomfort and disease. Hence the inlets and outlets must not be very near to the inmates, and the current must be divided.

5. The ventilation should, if possible, be self-acting after the amount required in a given room and under given conditions has been fixed.

6. Any general rule which may be laid down as to the number and size of the ventilators required in a room will demand modification by experience, since

room will demand modification by experience, since the admission of air will depend upon the elevation of the site, the direction of the prevalent winds, and the impediments which surrounding walls and buildings offer, and these cannot be the same on all

buildings offer, and these cannot be the same on all sides of a building.

7. Some differences in the plan, and much in the extent to which the plan should be carried, must depend upon the use of the rooms and the destination of the building, as to whether it be a private house, a public building with a fixed number of occupants, or a building, as a theatre, with a very varying number.

occupants, or a building, as a theatre, with a very varying number.

8. There is a relation between space and ventilation, for it is evident that with defective ventilation (not entire absence of ventilation) the larger the quantity of air in relation to the number of occupants the less the immediate evil, whilst at the same time, the larger the mass of air to be moved the greater is the force, or the more extended are the means, required to move it. In private houses, the cost is often unimportant, but in general, and particularly in reference to workhouses, hospitals, and other charities supported by voluntary contributions, the aim should be, by providing the best ventilation, to reduce space to the strict requirements of the occupants, and thus to utilize in the greatest degree the money to be expended. That relation must be determined by experiment. Both architects and amateurs are apt to give undue weight to the lofty, spacious, and handsome appearance of their buildings and too little to the solution of the problem of fitness with economy.

and too little to the solution of the problem of fitness with economy.

9. The test cannot be the life or death of the inmates, for health may be failing long before it ceases. Moreover, there are various degrees of health, and each person has a separate aspect of health, and it is not at all easy to indicate in particular cases the first period when some injury may have been done to it. A test is required by which we may infer that injury would result if the cause were continued, and this must clearly be derived from observation. A close-smelling or a foul-smelling room may not be immediately injurious to health, but it is disagreeable at the least, and as such should not be allowed; and although the most injurious emanations from the body are not offensive to the smell, their emission is accompanied by the injurious emanations from the body are not offensive to the smell, their emission is accompanied by the emission of offensive odours, and the two will coexist. There is thus a relation between them which may be made useful as a test, so that if in an inhabited room the air be foul to the sense of smell it may be regarded as injurious to health. But the

degree of relationship is not exact, since an unnegree or reasonsmp is not exact, since an incleanly person, or even a cleanly one, having the peculiarity of emitting strong odours in an unusual degree, will cause the air to be foul almost as soon as he enters, whilst another cleanly person may stay some time in the same room before rendering it offensive. Homes in realize the action to stay some time in the same room before rendering it offensive. Hence, in making the estimate, we must strive to ascertain whether the foul smell proceeds from dirty clothes, and particularly dirty stockings and unwashed skins, or is simply that which occurs with cleanly persons. When there is no offensive smell it may be assumed that the ventilation is sufficient; but as a certain amount of want of freshness, or closeness, is found in our bedrooms or other rooms without known injury to health. I am of rooms without known injury to health, I am of opinion that the ventilation is sufficient when the air, after the night's use, is not more offensive than is found in an ordinary private bedroom of the middle classes. Absolute purity of air in inhabited places, whether rooms, houses, public buildings, courts, streets, or towns, however desirable, is not necessary

to health, and is not attainable.

10. The test cannot be the means provided to 10. The test cannot be the means provided to effect the passage of a given quantity of air through a room in a given time, for if the ventilation depends upon natural agencies, it will vary with the force and direction of the winds, the impediments to their action upon a particular ventilator, the frequency with which doors are opened, and other varying causes. If the room went closed, except at parcauses. If the room were closed, except at particular places, and the air were, by artificial means, conveyed through apertures at a known rate, it would be possible. We do not, however, live in closed boxes, and we cannot separate ourselves from

closed boxes, and we cannot separate ourselves from the influence of natural causes.

11. Where persons do not occupy the same room or rooms throughout the 24 hours, but use other rooms, and particularly spend much time in the open air, defective ventilation of those rooms will be less injurious in proportion as they are used for a shorter region of time. period of time.

12. The cost of ventilating buildings is usually of importance. None can be so little as that mode which introduces the external air directly, but with proper safeguards, whilst all artificial systems are

expensive.

13. No system can be efficient, in a public institution, which depends upon windows, doors, and fire-places alone; but for thoroughly renewing the air on fitting occasions, it is desirable that there be fitting occasions, windows on both sides of a room, and particularly in

windows on both sides of a room, and particularly in public buildings.

14. When air is introduced on one side of a room only, whether by windows or by ventilators, the extent of its influence will vary with the conditions already named, but there is a relation also between it and the width of the room in reference to satisfactory ventilation. It is evident that, with little force of wind, the air will penetrate into the room but little, and with creater force the more; and also that, with and with greater force the more; and also that, with and with greater force one more; and any that, with a given force of current, the narrower the room the more certainly will it traverse it, and the wider the more certainly will it not traverse it. Hence, with such an arrangement, a wide room will be less perfectly ventilated than a narrow one, and a point perfectly ventilated than a narrow one, and a point may be readily reached at which the influence of such means of ventilation will be nil. Rooms with windows or ventilators on one side only should be very narrow, and still more so if there be no ventilation apart from the windows. A wide room, with windows only on one side, and no special ventilators which act permanently, must be ill-ventilated and unhealthy, as has been shown in the Nightingale Ward of King's College Hospital.

15. When air is introduced on two opposite sides of a room by windows or special ventilators, the current will usually extend further than twice the length of the current from one side of a room, and, as the wind will usually act upon one or the other as the wind will usually act upon one or the other side, the current will have greater force than with air openings on one side only. But there is a limit to the width of rooms so arranged, for, as the current must not be too great to be borne by those inmates who are placed near the external walls, its power to traverse the inner space is restricted. In very wide wards the ventilation in the middle is not so estimates.

so satisfactory as that near the external walls.

16. Where air is introduced into the centre floor of the room a current is produced in the part over which the inmates pass and repass, and is, therefore, very perceptible. Cold air in considerable quantity can rarely be introduced with propriety in that position, but warmed air might be borne.

Each room should be so constructed that its ventilation may be independent of that of staircase ventilation may be independent of that of staircases or any other room, but where two rooms are placed side by side with a partition wall between them, each having windows on one side only, the ventilation of each is improved in proportion as a part of the partition wall is removed. Thus, one room may improve the ventilation of the other, and both be as if they had windows, or ventilators, on both sides.

18. Ventilators should be placed on opposite sides of a room, be of small size, sufficiently numerous to affect all parts of the room, defended on the inside by finely perforated zinc, and be placed at the floor level and ceiling level.

19. Ventilators in a small part of a room only are insufficient for ventilation, since when a current of

goes in a direct line, and does not greatly mix with the air on either side of it. This may be readily seen when smoke is admitted by an inlet and emitted by an outlet ventilator, or such an arrangement as exists in prison cells.

exists in prison cens.

20. Where the conditions rapidly vary, as in churches, chapels, and theatres, it is impossible to devise a system which will not require modification devise a system which will not require modification by an intelligent person. At present, the system is universally defective, and only after the heat has become great and the persons very sensitive to cold are the doors or windows opened. The aim should be to regulate the admission of air from the moment when persons enter, so that the temperature shall never be materially increased, but remain at, say, at before, in winter, and 62deg. in summer. Cool air, without draughts, is better borne than hot air with intermittent draughts. In very lofty rooms the apertures for the admission and emission of air should be below the top, not too far removed from the occu-pants of the seats, the sources of the heat. In addition to this, however, ventilators should be placed in various parts of the ceiling, and be kept under con-

various parts of the ceiling, and be kept under control by a competent person.

21. Such rooms should be thoroughly aired after every occasion of their use, by the full opening of windows. At present, with three services at a church or chapel, this is neglected, and the air is close, heavy, and foul in the afterneon and evening.

22. No artificial means of ventilation should be relied upon solely, which will not act by day and night throughout the year. Hence, with ventilating stoves, which are very valuable, and ventilating air-flues, there should be other and self-acting means of ventilation. of ventilation.

In conclusion, it may be useful that I should sum up the principal errors into which architects are now falling in the systems of ventilation which they recommend. They are:—

1. In not duly estimating the practical limits of the law, that heated air ascends, and the relation of

numbers of inmates and size of rooms in the application of the law.

2. In not duly considering that air shafts, acting under that law, cannot act in all seasons, and with and without fire alike.

3. In not duly estimating the amount of air which can be admitted by windows and doors alone.

4. In not duly estimating the practical limits to which an entering current may be carried, whether

from one or both sides of a room.
5. In not duly considering the effects of currents upon inmates, and the limitation thus demanded upon the amount, force, and elevation of currents.

6. In not duly estimating the inverse relation of

ventilation to temperature in its effect upon inmates, and particularly upon the old and the young.

7. In not duly estimating the influence of the winds, and the impediments of surrounding buildings, &c., upon each aspect of a building.

8. In having incorrect views as to the direction

of the current through ventilators at different eleva-

# FIRE TELEGRAPHY.

THE systems of fire telegraphy now in use in THE systems of fire telegraphy now in use in Boston, Chicago, Cincinnati, St. Louis, New Orleans, Philadelphia, Baltimore, and other cities, have been working for several years, and in no case have they failed to give great satisfaction. New York, says an American journal, has been behind most ofher sistercities. But it is proposed now to consider the subject of introducing a complete system, taking all the features which, in other cities, have proved reliable and good, and adding to them such appliances as have been brought out in the last three reliable and good, and adding to them such appliances as have been brought out in the last three or four years in the science of electric telegraphy to perfect the reliability and usefulness of the New York system far beyond all others. The general system consists in the setting up a number of iron street boxes at the positions designated by the department. These boxes are opened by responsible people, who are trusted with the fire key. When opened, an inner box is disclosed with a bell-pull upon it. This is drawn down when an alarm is to be given, and a piece of mechanism, closed up in a be given, and a piece of mechanism, closed up in a third tight box, is set in action, telegraphing with third tight box, is set in action, telegraphing with automatic exactness the number of the locality, removing the possibility of false alarm by an excited or incompetent person. The message or number is instantly struck on a bell and printed on a recording instrument at the central office, where an operator stands ready to receive it day and night. The great accuracy of the iron box machinery enables him to read the signal the first time it is sent, although the boxes are made to repeat the signal three, four or five times, as they may be adjusted. Having heard the alarm, the operator turns to another instrument of very elaborate construction, by means of which an automatically perfect alarm is sent to such places as

necessary for such an extensive telegraph is not requir.d. as it transmits successive powerful ways of electricity from the same battery to the successive lines which make up the grand system. The alarm lines which make up the grand system. The alarm machines are arranged to dispense with batteries now usually employed at the alarm stations—the machines being wound up and the electric current simply releasing the machinery. On this principle bells of any weight can be rung—one of 140b. bing during the exhibition-as easily as rung du smallest.

rung during the exhibition—as easily as the smallest.

These are the chief features of the general system. In addition is a system of magnets, called test magnets, with which it is the duty of the operator in charge to try his lines every twenty minutes, his trials being so recorded that he cannot omit any test on any line without detection, and the daily condition of all lines being recorded for reference. The improvements proposed and exhibited consist in the abandonment of the earth circuit, substituting for it the low tension metallic circuit; thus practically removing nine-tenths of the difficulties incident to telegraphy, such as escapes and high tension currents. This was very clearly demonstrated by placing two sets of lines in the earth. In one case making the earth form one part of the circuit, and in the other case burying the wires, which formed an uninterrupted metallic circuit in the earth. In one case a leak or escape completely cut off the instruments at one position of the line: in the second case no apparent effect was produced in the same instruments. Another improvement was shown to be the building of circuits of wire, so interlaging each other ments. Another improvement was shown to be the building of circuits of wire, so interlacing each other that no two neighbouring boxes or stations are placed on the same line. A third, in the introduction of a conducting wire for dangerous places, more highly insulated than if covered with glass. A fourth, an immense improvement in the introduction of a battery, costing in maintenance less than one-fifth battery, costing in maintenance less than one-fifth of those now in use, or running a year without taking to pieces, and giving a current so uniform as to almost supersede the usual necessity for adjustment, and facilitating the system of testing. This new system enables the operator in his office to ascertain quickly the condition of his line, so as to keep it precisely to the required standard to tell the position of breaks and troubles, being the result of the investigation of philosophers who have made the working of the Atlantic cable such a wonderful success. The operator then from his office can feel the condition of all his lines, and give intelligent directions for their care and preservation.

directions for their care and preservation.

The incidental advantages of such a system are the establishment of a most complete system are, the establishment of a most complete system of protection from lightning. In every box is a perfect arrester, so that any amount of the fluid, periect arrester, so that any amount of the much having so many means of access to the ground, is easily dissipated. The statistics of several cities and towns prove this. Secondly, the setting up in each iron house of a complete telegraph office, it being easy for a skilful telegraphist, having access to the inner part of the box, to place himself in consection with the central office sculing and received being easy for a skilful telegraphist, having access to the inner part of the box, to place himself in connection with the central office, sending and receiving intelligence. It is thus proposed to build the best possible lines, place upon them the most accurate machinery, take from the operator, often excited and nervous, the responsibility, the burden of confusing details, facilitate the most speedy possible reception and transmission of alarms, saving thus the precious seconds at the very commencement of a fire, giving the superintendent, also, the amplest facilities for testing and watching his lines, bringing down the responsibility to one man, and then watching and recording his acts.

# THE NAIL TRADE IN THE MIDLANDS.

THE following interesting remarks upon the manufacture of nails appeared in a recent number of "The Engineer":—The manufacture of wrought or forged nails is one of the oldest crafts in the Midlands, and although authentic records of its earlier history are wanting, there can be little doubt that it flourished in Queen Elizabeth's time when the fabrication of hadware in Birtime, when the fabrication of hardware in Birmingham and the surrounding district first began to develope. Halesowen and Dudley were perhaps the great "centres" of the trade up to the middle of the last century, since which time it has been more widely distributed, and it now constitutes the "staple" of the following localities, in addition to the two named, viz., Sedgely, Gornal, Cos-ley, Womborne, Wordsley, Rowley, Netherton, Cradley, Lye Waste, Oldswinford, Stourbridge, Bromsgrove, Northfield, Harborne, Tipton, Oldbury, Darlaston, Pelsall, Burntwood, and Westbromwich.

A feature of nail-forging, which distinguishes the craft from most others in this district, is that the workpeople are nearly all employed at their own homes as "outworkers" for the factors. Most of the cottages in the localities named have Most of the cottages in the localities named have automatically perfect alarm is sent to such places as the regulations of the department designates, it being competent to send it to every engine-house, or only a few of them—to overy or only a few of the iron boxes, thus enabling the passor-by in any part of the city to hear the locality of the fire. The machine is easily able to send to 1,000 places, but it is also arranged so that the immense battery usually

anvil, the head of which is not much larger than the face of the hammer. Each nailer, with his family, making only one description of nail all the year round, only one heading-tool is required to each hammer. Every square foot of space in and about the forge, Mr. Burritt tells us, is utilized. If the nailer and his wife or daughter are the only members of his family to use it, he often lets one or two "stalls" to his neighbours for 8d. each per week. That is, for this rate of rentage he lets a neighbour heat his rod in the same fire and make nails on the other side of the forge. I have seen four girls of about sixteen years of age standing around the same forge at once, each with her rod in the fire. The coal used must be lighter and more smokeless than anvil, the head of which is not much larger than the coal used must be lighter and more smokeless than the common sea-coal, which is apt to form a crust over the fire, thereby preventing the admission of small rods. They therefore use a kind of coke, called breese, worth 6d. to 7d. per sack of three bushels.

The nailmaster, or factor, is practically the employer of the nailer, although exercising, of course, no control over the latter, compared with the surployer of the latter, compared with the surveillance exercised by employers in large factories.

Mr. Ephraim Ball, who has been engaged in the trade for many years, aptly describes the modus operandi of the nail factor. On commencing business, he opens a warehouse in one of the nailing villages, but to carry on a large trade in all descriptions of but to carry on a large trade in all descriptions of hammered nails he must have supplementary ware-houses in various parts of the dietricts. At each of these warehouses, on certain days of the week, nail-rod iron is delivered to the nailmaker sufficient nail-rod iron is delivered to the nailmaker sufficient for him and his family to work up in a week, and at the expiration of that time he is expected to return the iron made into nails, when he receives a further supply. The length, thickness, shape, &c., of handmade nails are very numerous, and in nearly every district a different class of nails is manufactured. Those, for example, made in the districts around Dudley are not made in the neighbourhood of Bromsgrove. Among the leading descriptions of wrought nails are—Tea-chest nails, horse nails, slate nails, mule nails, hob nails, and gate nails, slate nails, mule nails, hob nails, and gate nails. The number of nailmakers in this district in 1830 was over 50,000, but at the present time not more than 20,000 are employed. The cause of this diminution is readily explained. Up to the date named (1830) all nails were either hammered or cast, and the demand for the former description especially was something prodigious. The Government contracts for the Admiralty alone averaged 600 tons of nails per annum, and the London Dock Company and the for the Admiratty alone averaged 600 tons of nails per annum, and the London Dock Company and the East India Dock Company each sent into this district orders for large quantities of tea-chest nails. The demand from the United States and Canada was likewise very considerable. Almost the whole of these sources of demand are now practically closed to the wrought nail trade.

About the real 1830 companied the manufacture.

About the year 1830 commenced the manufacture of nails by machinery, the effect of which has, naturally, been disastrous to the hand-made branch, of nails by machinery, the effect of which has, naturally, been disastrous to the hand-made branch, and the industry has ever since been steadily dying out. As early as the year 1837 it was found necessary to reduce the rate of nailers' wages, at that time over the average of artizan's earnings in the district. This step was necessitated mainly by the machine-nail competition, but it was perhaps accelerated in some degree by the rivalry of hand-made nailers in Belgium who seld their productions at artenishingly low prices. It was the germ of that formidable rivalry which the South Stafforshire iron trade has since experienced from the "Black Country" of Belgium. In 1838 a second reduction took place, and competition from the quarters indicated became so increasingly severe, that in 1842 a still greater "drop" was announced, to the consternation of the whole district. At this the nailers showed a determined resistance. On the 25th of April a rising of 20,000 nailers took place to protest against the proposed reduction, and to condemn the obnoxious truck system, which even at that time was prevalent in the trade. A monster meeting was held in the open air. The mob marched to Dudley, taking with them as prisoners several nail factors, who, having offended, had been scized by main force, and dragged along amid the jeers of the infuriated multitude. The military was called out. The Riot Act was read. Yet a monster demonstration was held, and the crowds were with difficulty dispersed. Mr. Ball informs us, as a fact worthy of notice, that the mon grossly ill-treated some of the best money-paying masters in the trade, and for this treatment they paid a heavy penalty. The trade was left to take its course. No meeting of masters to regulate wages took place for some time, and reductions of wages were made in two of masters to regulate wages took place for some time, and reductions of wages were made in two years of 20 per cent. to 30 per cent. Since that period, the history of the wrought nail trade has been a monotonous chronicle of strikes and disputations, and wages are now reduced to the lowest ebb. At the best of times, the average weekly earnings of a nailmaker are not more than 12s. to 16s. per week, and there are many who only carn 10s. Women's wages average 7s. 6d., and children's 4s.

THE death is announced of Robert Scott Lander, B.A.S., one of our best known Scottish painters. He was born in 1803.

## COURT OF COMMON PLEAS. April 27.

(Sittings in Banco, Easter Term, before Lord Chief Justice Bovill and Justices Krating and Smith.) EDMUNDS v. GREENWOOD.

In this case, the Attorney-General, the Solicitor-General, Mr. Field, Q.C., and Mr. Archibald, showed cause against a rule obtained by Mr. Digby Seymour, Q.C., calling upon the Crown to show cause why an order of reference should not be drawn up embodying the terms of agreement for a reference signed by the counsel for the plaintiff and the counsel for the defendant, or why the agreement should not be cancelled, and the cause be restored to its place on the list for trial.

Mr. Digby Seymour, Q.C., and Mr. Tindal Atkin-

son supported it.

On the part of the Crown it was urged by the learned Attorney-General, and also by the learned Solicitor-General, that the Crown was prepared to meet any action the defendant thought right to bring, or, if he chose to refer his action against the Crown, to refer it. As to this rule, it was endeavoured to make the Court interfere with the terms of reference agreed upon on the ground that Mr. Edmunds had been misled, and that the Crown being in the wrong, ought to do that which was right. The action was for an alleged libel by Mr. Greenwood, the solicitor to the Treasury, in a report made by Mr. Greenwood and the late Mr. Hindmarch on certain alleged defalcations and misappropriations of money by the plaintiff while holding an office under the Crown. It was sought in this action against Mr. Greenwood, which had been agreed to be referred, to import the torms that the arbitrator should consider any claims which the plaintiff had morally or legally against the Crown. The action against Mr. Greenwood was one thing, the supposed claims made against the Crown another. It had been agreed that the stet processus in the action should be no bar to any supposed claim against the Crown, but that was a very different thing from making those supposed claims a substantial ground of reference. If they were made a substantial ground of reference, the arbitrator must entertain them; if the reference was to be no bar to those supposed claims, the arbitrator in the action referred would probably not entertain them. It was also sought to make the arbitration public, and it was a most unlikely thing that the counsel for the Crown should ever have assented to such terms of reference, and both the Attorney-General and the Solicitor-General distinctly asserted that they never had agreed to or signed any such terms.

After much difference between the learned

Attorney-General and the Solicitor-General, on the one hand, and Mr. Digby Seymour on the other, as to what had been agreed upon as the terms of reference, and as to what had really occurred,

The Chief Justice said nothing could be simpler than the terms signed by the Attorney-General. It seemed to him that the order of reference drawn up by Mr. Edmunds departed from that, and he ought not to have moved this rule. As the order was drawn up by Mr. Edmunds, it was made imperative on the arbitrator to hear the claims which Mr. Edmunds supposed he had, moral or legal, That, by the terms signed against the Crown. the Attorney-General, was never intended. rule was to draw up an order of reference, embodying the terms of the reference signed between the counsel. There could be no difficulty in doing this, and if the parties could not agree, let it be

The Attorney-General.—I have always been ready to do that. I do not think the Crown ought to have been brought here.

After some further argument.

The Chief Justice said it would be better for all parties to have the matter finally settled, without costs, as he had suggested.

The Attorney-General said he was in the hands of the Court.

Mr. Justice Keating.—Let the whole terms in the action of "Edmunds v. Greenwood" be embodied in a rule of this Court, so that there can be no further dispute.—Rule accordingly.

### ROLLS COURT. April 28. DAW v. BLEY.

HIS LORDSHIP gave judgment to-day in this suit, which has been instituted by Mr. Daw, the gun- thus terminated their labours.

maker, against Messrs. Eley, to obtain a declaration that a metal cartridge, manufactured by them, is an infringement of a patent taken out by Mr. Daw, in March, 1867, for an invention of metallic soldered cartridges, for which he obtained the prize of £400 offered by Government for the best cartridge. Our readers are well aware that Mr. Daw's invention consists of an improvement upon the old metallic cartridges, which consisted of a cylinder of metal, folded so as to form two layers unsoldered together, with a lining of paper. The defect of this form of cartridge, was that it frequently clogged the gun. The plaintiff makes his cartridges of a cylinder of very thin metal, one edge only overlapping the other, and soldered or cemented to it. e main points of the invention, as stated in the specification, were-first, the thinness of the metal; secondly, the overlapping edge instead of two or three layers; thirdly, the use of cement or solder. Each of these characteristics were well known before the patent. The plaintiff maintained the combination was now.

His Lordship, however, held that the combination did not constitute a new invention, and that the plaintiff's patent, being, consequently, worthloss, his bill must be dismissed with costs. In consequence of holding this view, his lordship did not consider it necessary to enter at length into the question of novelty of invention, being, nevertheless, of opinion that the same combination had been previously invented and published by a Mr. Rochatte, who had sold his invention to Messrs.

Mr. Jessel, Q.C., Mr. Manisty, Q.C., Mr. Macrory, and Mr. Roberts appeared for the plaintiff; Mr. Southgate, Q.C., Mr. Grove, Q.C., Mr. Aston, and Mr. Langley for the defendants.

### TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 is. 8d. yearly, or 10s. 10d. half-yearly payable in advance

advance.
All literary communications should be addressed to the Editor of the MECHANICS MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS MAGAZINE Office, 166, Fleet-street, London.
To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday exeming.

Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ep. M. M.

faith. Eb. M. M.
Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d, per line, or 5d, per line for 13 insertions, or 4d, per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

# SHIPS OF WAR.

TO THE EDITOR OF THE "MECHANICS" MAGAZINE

SIE,—As regards the originator of the twin screw mode of propulsion, I think we are all agreed that the late Mr. G. Rennie was the first engineer who practically tested the system. While engaged with the firm, I was early enlightened as regards the merits of twin screws. In 1864, I proposed a navigable dock, to the Lords of the Admiralty, suited to lift the "Warrior." It was arranged so as to follow a fleet in time of war. The mode of propulsion I advocated was "twin screws" (your readers will see the form I proposed by referring to your magazine). As regards my present proposal, I have not deemed it necessary to present it to the officials at Whitehall. Your correspondent must know that I do not advocate the Moncrieff system in its best application—namely, to land forts—without a covering; but this I advocate, that the Moncrieff is as well suited for ships of war as any system we have in the Royal Navy. The ships are nothing but huge turrets; strong on the sides and very weak top and bottom. A shot, vertically fired, will go right through them, and had "F. H. R." looked into the form of turret proposed for the new ships he could not fail to observe that the revolving turrets have no covering at top, although a covering may be fitted. He will, likewise, see that the turrets are -As regards the originator of the twin screw not tall to observe that the revolving unrets have be fitted. He will, likewise, see that the turrets are protected with a shield at the bottom. One shot hitting the shield would disable the turret; it would be jammed in its place, and all the force exerted through the medium of wheels would not move it. There are too many wheels in all turrets which are made to revolve; the complication is fearful, but nothing to the complication of a ship of war wholly unprotected from vertical fire. My twin structure, 1 am aware, is rather startling; the form is new, and there can be no doubt that it would tend in some there can be no doubt that it would tend in some cases to lessen the midship area. A river of water flows through the "Hercules" or vessels of that type; but is the U form the most stable, or is it the best form to suit ships of war, as regards speed? I think not, and, as regards percussion, the "Hercules" would never give a second blow at full

speed.
What we require in ships of war is breadth. authorities may make as many ships as they choose strength cannot be got into them without heavy scantling; and even then they are not suited for perscanting; and even then they are not suited for per-cussive warfare. I maintain my twins are, as like-wise for modern warfare, combining great strength with speed. In another arrangement, I have intro-duced fixed covered turrets, along with broadsides. As I stated, we have no experience with or without turrets, and in mechanical applications we must simply study what would be the effect of an elon-gated shot on the various proposals. I think the cone is better than the revolving turret, no top pro-tection in either to be accepted.—I am. Sir. yours. tection in either to be accepted.—I am, Sir, your &c.,
John G. Winton.

13, Gladstone-street, St. George's-road,
April 24.

# EDWARDS' TRAIN SIGNALS.

SIR.—In an article in your last impression, describing my system of train signalling, you state that if a greater amount of indraw than 18in, or 20in, is necesary, the system is useless. Permit me to state that this is not so. The amount of indraw can be increased this is not so. The amount of indraw can be increased to 3ft. 10in. momentarily; and with the modified plan, where no detectors are used, any amount of indraw can be made—even 50 yards, if necessary—and signals given through any number of carriages.—I am, Sir, yours, &c. JOHN EDWARDS. 157, Richmond-road, Hackney, April 23.

# SHEATHING IRON SHIPS.

SHEATHING IRON SHIPS.

SIR.—From an article in your issue of last week, it appears that no reliable, and certainly no economical, plan has yet been tried to effect the sheathing of iron ships. All the methods tried or proposed appear to me to be mere makeshifts, and tending to diminish rather than add to the strength and durability of the structure, and they are all very costly, to boot. I have on former occasions advocated a plan of sheathing iron ships, which I.—like most others who have plans to propose—feel convinced, would, if once fairly tried, settle this vexed question. But I shall let the proposal speak for itself. I may premise, however, that in working it out the details can be considerably varied.

I shall begin with laying down a wooden keel;

as may be desired, perhaps no farther than load line. To these wooden frames nail the wood sheathing; 6in. broad and 4in. deep for these wooden frames and sheathing of about 2in. thick may be a fair scantling for a ship of large size. A wooden stem and sternpost would complete the outside casing, on which either copper or zinc could be nailed in the ordinary way. All this woodwork can be securely attached to the iron hull without a single bolt-hole being either tapped into or pierced through it. The iron hull would be intact; even the wooden frames could be attached by brackets without a single bolt-hole being in them either.

It will be perceived that there is a space of 4in., (the depth of wood frames), between the wooden sheathing and iron hull. Now, it is evident that were this space filled in with some adhesive and slightly elastic material, great additional strength and durability would be gained, and any galvanic action that might exist between the copper and iron would thus be completely cut off. Various substances could be suggested as suitable for this purpose. In the case of this space not being filled up, the keelson should have the form of a hollow girder, made completely watertight, and any water the vessel might make through the sheathing should be

pose. In the case of this space not being inied up, the keelson should have the form of a hollow girder, made completely watertight, and any water the vessel might make through the sheathing should be conveyed there—and there only—to the pumps.

With regard to cost, we have the wooden frames and sheathing, wooden keel, wooden stem, and wooden sternpost, and workmanship on these all extra from an ordinary iron ship. Per coutra we save the expense of iron keel, iron stem, and iron sternpost, all very expensive articles. We save also considerably in workmanship on the iron department, which would be got up with much less expense than now. Everything considered, it is questionable if first cost on this plan would go much, if anything, beyond the mere iron ship. But when we come to look into the probable cost of the various methods that are being tried to gain the same ends, this one will be found to be beyond compare the least expensive, and, as I have already said, I feel convinced it would also be found to be by far the most effective.

—I am, Sir, yours, &c., -I am, Sir, yours, &c., April 28.

# Nabal, Military, and Gunnery Items.

THE last monthly statement, issued by the Bureau Veritas, of Paris, shows that during the month of March last, 299 vessels, including 16 steamers, were reported as total losses. The casualties were distributed among different nationalities as under:—124 English, 58 French, 32 North German, 15 American, 13 Italian, 9 Greek, 9 Norwegian, 6 Austrian, and 33 hospital reprises the flags. bearing various other flags.

THE American steamer "G. A. Thompson" struck THE American steamer "G. A. Thompson" struck a snag on Arkansas river, in Arkansas, on the night of the 9th inst., and was a total loss. She had on board eighteen passengers, and was laden with a cargo containing lime, which slacked on getting in contact with the water, set fire to the boat, and severely burnt several of the crew and passengers. Seventeen lives were lost by burning and drowning. The line of Count Tilly, the celebrated opponent of Gustavus, in the Thirty Years' War, has just become extinct by the decease of Count Charles Gustavus Edward Augustus von Tserclas Tilly, at the ripe old age of 85. He had been Chamberlain to the King of Holland, and a member of the Equestrian order of

age of 85. He had been Chamberlain to the King of Holland, and a member of the Equestrian order of Brabant, and was the last direct descendant of Eve-rard von Tserclas Tilly, the liberator of Brussels in 1356, and of his descendant above alluded to, who was generalissimo of the Catholic League in the 17th century.

On Saturday morning, Joseph Cawthorn, a native of Newark, died at Sunderland, at the age of 79. The deceased, who had volunteered into the Rifle Brigade, fought in nearly all of the hotly-contested engagements in the Peninsula, as well as at Waterloo, where he was wounded. He received his discharge in 1819 without a pension. In 1866, he was in the receipt of a pension of only 1s. per day, and this was obtained by the most strenuous efforts on his behalf.

THE report of General Sir J. Hope Grant, on the The report of General Sir J. Hope Grant, on the Easter Review of Volunteers at Dover, is just published. It speaks in the highest terms of all the arrangements, and particularly those of the South-Eastern and other railway companies concerned; but, while giving credit to the Volunteer force for willingness and intelligence, the general's report contains the following ominous sentence:—"In my opinion, this force cannot be really serviceable, if it be not placed, while under arms, under some more stringent military control. Such a large body of armed men not amenable to any military discipline might be the cause of very serious embarrassment."

CAPTAIN JOHN GRORGE PHILIPPE the last sur-

co-operated in the siege of Genoa, and took part in the operations of 1801 in Egypt. He also served in one of eight boats cutting out the "Esmeralda" and "Pas," Spanish corvettes, in Barcelona roads, in 1800. From 1802 until prometed to Commander, in 1814, he was employed successively on the home and North American stations, in the Channel, on the north coast of Spain, at Portsmouth, at Newfound-land, in the Baltic, and in the Downs.

# Miscellanen.

THE third pumping engine for the Brooklyn Water Works, now being built, will be the largest and most powerful pumping engine in the world, with the exception of one in Cincinnati.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending April 24, was 3,937. Total number since the opening of the Museum, free daily (May 12, 1858)

THE master and fellows of Trinity have decided to entrust to Mr. Woolner the execution of the monument to Dr. Whewell, which is to be placed in the ante-chapel of the college. The statue of the late master will stand next to that of Lord Macaulay, some little distance to the right of Roubilliac's well-known statue of Newton.

known statue of Newton.

WE ("Athenseum") hear with great pleasure that the Subject Catalogue of the MSS. in the British Museum is making good progress in the energetic hands of the Keeper of the MSS. and his able assistants. The first drafts of the work have been already made and bound in portly folios, and the rest are going well ahead. These will form the groundwork of a fresh and complete description of the whole of the MSS and fully described in the old catalogue. the MSS. not fully described in the old catalogue.

THE number of gallons of proof spirits distilled in the United Kingdom was 26,750,684 in 1865, 25,567,962 in 1866, 23,323,613 in 1867, 24,928,155 in 25,567,362 in 1866, 23,323,613 in 1867, 24,922,135 in 1868. The quantity retained for consumption in the United Kingdom as beverage was 20,811,155 gallons in 1865; in 1866, 22,216,390 gallons; in 1867, 21,199,376 gallons; in 1868, 21,008,634 gallons. All this time the population was increasing by, at all events, 1 per cent. per annum.

THE number of visitors to the South Kensington The number of visitors to the South Kensington Museum during the week ending April 24, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 14,175; Meyrick and other galleries, 3,048; on Wednesday, Thursday, and Friday (admission 6d.) from 10 a.m. till 6 p.m., 2,623. Meyrick and other galleries, 245; total, 20,091. Average of corresponding week in former years, 12,787. Total from opening of Museum, 8,375,877.

12,787. Total from opening of Museum, 8,375,878

A PARLIAMENTARY paper showing the amount of coinage at the Mint during the last ten years past was issued on Wednesday. In 1868 there were coined in gold, 1,653,384 sovereigns; in silver: 896,940 florins; 3,330,360 shillings; 1,069,200 sixpences; 4,158 fourpences; 1,461,768 threepences; 4,752 twopences; 7,920 pence; in copper: 1,182,720 pence; 3,046,400 halfpence; 4,851,208 farthings. No half-crowns have been coined since 1851. Worn silver of the nominal value of £125,000 was purchased for recoinage, the loss on which was £18,058.

chased for recomage, the loss on which was £18,058.

The second spring flower show of the Royal
Botanic Society was held on Tuesday in the gardens
of the society in Regent's Park. The show, considering the early period of the year, was an exceedingly fine one; the roses, especially, were presented
of a size and beauty hardly to be exceeded in the or a size and beauty harmy to be exceeded in the shows later in the season. Some splendid standard azaleas were exhibited by Mr. C. Turner, of Slough. There were also a very fine display of flowers in the miscellaneous classes—cinerarias, amaryllis, lilies of the valley, auriculas, &c.

lilies of the valley, auriculas, &c.

A LARGE fan, on the Guibal principal, was started at the Byers Green Colliery on Monday week, and did good work. It was run up to 60 revolutions per minute, and at this speed produced 68,000 cubic feet of air per minute, with a water gauge of 3-10 in. The quantity of air previously got by the furnace was 11,000 cubic feet below the quantity produced by the fan, or 57,000 cubic feet. The fan has not yet been worked up to its maximum power, as it is guaranteed by the maker to work up to 70 revolutions per minute. The makers are Messrs. Black, Hawthorn, and Co., of Gateshead.

alan of sheathing iron ships, which I—like most others who have plans to propose—feel convinced, would, if once fairly tried, settle this vexed question. But I shall let the proposal speak for itself. I may premise, however, that in working it out the details can be considerably varied.

I shall begin with laying down a wooden keel; on this keel put up, say, one-half of the iron frames, then plate on these frames as usual, but the plating and riveting need only be done in the same style Rivet heads may be either inside or outside, and the plating would not demand exact shearing, as now. When the plating is finished, attach the other half of the iron frames outside the vessel's plating, spaced midway between the inside ones. Alongside of these outside iron frames, running from keel to gunwale, or so far up

THE manufacture of soap may now be added to the list of the local industries of Adelaide, a soap-boiling factory having lately been established at Port Macdonald, capable of producing about two tons of soap weekly. Besides the advantage of an important local industry in connection with this manufacture, the butches will how find a ready market for tallow the butchers will now find a ready market for tallow and fatty refuse, and the money hitherto sent out of the colony for the purchase of soap will, in part at least, be kept there for profitable employment.

A SERIOUS accident happened at some extensive Cornish slate quarries, at St. Teak's, on Wednesday Cornish slate quarries, at St. Teak's, on Wednesday week. The pits are near Camelford, and excavated by the uninterrupted labour of centuries, are encompassed by mountains of rubbish. The slate is obtained at a depth of 260ft., and drawn up to the surface by a projecting pulley, rigged in what is called a papote head, and, with its gear, of tremendous weight. A large number of men were at work weight. A large number of men were at work below, when the papote head gave way, and many were buried beneath the mass. Twenty-three were got out speedily, but nine were dead, and the others severely injured. The total loss of life is at present the men are yet missing. unascertained, as many of the men are yet missing.

A PEARFUL catastrophe is reported from the mining regions near Gold Hill, Nevada. On April 7, a fire broke out in the shaft of the Yellow Jacket Mine, and soon communicated, through underground passages, to two neighbouring mines known as Brown Point and Old Kentuck. The fire was ex-Brown Point and Old Kentuck. The fire was extinguished after burning fiercely for three days. Forty lives were lost, and the bodies of the dead have not yet been all recovered. These mines have been carried to a great depth in the earth, and the been carried to a great depth in the earth, and the subterranean passages extend through a wide space. The heat at all times is great, 100deg, of Fahrenheit being the usual temperature, and dried the timber used in the shafts and passages, so that when the fire began it spread with rapidity. It was extinguished by stopping all the outlets at the surface, and injecting steam, thus smothering the sames.

and injecting steam, thus smothering the flames.

At the last monthly general meeting of the Zoological Society, held at the society's house, Hanover-square, Viscount Walden, president, in the chair, Colonel C. H. Hutchinson, Captain J. G. Noble, Captain J. W. T.Bulkeley, Mrs. Mary Ann Coleman, Miss Emily Routledge, and Messrs. A. A. Smith, C. Branch, N. Bradford, L. A. Mansse, A. R. Tull, E. R. Alston, F. F. Simond, E. Rayner, William Fairlie of Holmes, Robert P. Wilson, William S. Smith, Henry A. Blythe, Alfred Gillett, Charles Russel, John Gordon of Cluny, Henry Johnson, T. P. Tindale, William Todd, F. W. Lucas, William Westley, J. B. Austin, S. O'Brien Hoare, Henry Gaskell, and S. Russell were elected Fellows, and Mr. John Brazier, of Sydney, New South Wales, a corresponding member of the Society. Thirty-three candidates for the Fellowship were proposed, and ordered to be balloted for at the next meeting of the society. of the society.

THE following notification, dated Board of Trade THE following notification, dated Board of Trade, April 12, appeared in the "London Gazette" of the 13th inst.:—With reference to the notice inserted in the "London Gazette" of January 1 last, stating that the Argentine Government had offered a prize of £1,000 for the best system of preserving fresh meat, the Board of Trade have received from the meat, the Board of Trade have received from the Secretary of State for Foreign Affairs a copy of a further despatch from Her Majesty's Minister at Buenos Ayres, reporting that the Government of the Argentine Confederation have issued a further decree, to the effect that the prize can only be obtained by those persons who, whether at home or abroad, have carried out their discovery in practice, and who produce the result at the Ministry of the Interior, in order that the scientific commission which will be named for that purpose may, after examining the results, adjudge the prize to the one offering the greatest advantages at industry. As a consequence of this decree the period for the presentation of proposals has been extended till August 31 next.

# Patents for Inbentions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—3114, 3121, 3125, 3138, 3141, 3153, 3157, 3159, 3172
GENERAL MACHINERT—3114, 3116, 3122, 3123, 3136, 3143, 3145, 3146
LIGHTING, HEATING, AND VENTILATING—3116, 3124, 3132, 3133, 3151, 3154, 3160
METALS, including apparatus for their manufacture—3112, 3123, 3148
MISCELLANEOUS—3115, 3116, 3118, 3119, 3127, 3128, 3130, 3142, 3149, 3150, 3155, 3162, 3168
BOADS AND VENICLES, including railway plant and car riages, saddlery, and harness, &c.—3111
SHIPS AND BOATS, including their fittings—3120, 3122, 3134

3134 Steam Engines—3114, 3169 Warfare—3115, 3131, 3134, 3164, 3165, 3173

3111 F. BARNETT, Paris. Artificial paving. Dated October 10, 1868.

ber 10, 1868.

This consists in the manufacture of a material suitable for forming roads and pavements, which is called "iron asphalte." Its composition is, of natural or artificial bitumen, 45 parts; of natural sesquioxide of iron, or of pulverized iron ore, 45 parts; of purified mineral tar, 10 parts.—Patent completed.

10 parts.—Patent completed.

3112 T. Merz and G. Thomson, Hebburn, Durham.

Calcining ores. Dated October 10, 1868.

This consists in applying a revolving furnace, such as that used in alkali works, for transforming sulphate into carbonate of sods, to the calcination of ores, minerals, and other substances, especially copper ores, or copper ores mixed with sait or other chlorides. In addition to the revolving furnace, smokeless fire gases or fiames are employed for heating the furnace. These may be obtained by burning a suitable combustible gas, such as coal gas or carbonic oxide, or by burning coal, or other solid fuel, in a furnace, arranged so as to insure the absence of smoke.

—Patent completed.

3113 R. Too Leith, N.B. Separating partially ground.

—Patent completed.

3113 R. Top Leith, N.B. Separating partially ground grain. (A communication.) Dated October 10, 1863.

Three modifications of apparatus are comprised in the invention, and in two of these the exhaust action of a blowing fan, or its equivalent, is employed to accomplish the separation and cleaning, whilst, in the third, the blowing action of the fan is used in a similar way.—Patent completed.

completed.

3114 S. J. MACCARTHY, Charlotte-street, W. Securing boots and thoes. Dated October 10, 1868.

The edges of boots or shoes which it is desired to close or hold together are attached to flexible ribs, grooves, or guides formed of "dexible metal" links or chain of suitable form. Upon, around, or within the flexible ribs a sliding-piece, formed of metal, is arranged, which is so formed as to be readily moved along the ribs, but which is always retained upon both of them. The sliding-pieces are so formed as to bring the two edges of the article as near together as may be desired at that part where the sliding-piece is placed, and when the latter is withdrawn from, or moved to, one end of the flexible ribs, the edges of the material to which they are attached can be opened, loosed, or separated from one another.—Patent completed.

pleted.

3115 F. A. ABEL and E. O. Brown, Woolwich. Firing explosives. Dated October 10, 1868.

A small cylinder or tube, closed at one end, and consisting of metal, wood, paper, papier mache, cardboard, or a combination of these, is charged with a small quantity of fulminate of mercury (say, from 10 to 30 grains, if a metal tube be used). A loose plug of gun cottom is inserted over the fulminate, so as to confine the latter in the closed end of the tube. The open end is then closed with a piece of thin paper, which may be varnished to exclude moisture.—Patent completed.

3116 W. H. ST. AUBIN and B. BENTON, Wolverhampton.

clude moisture.—Patent completed.

3116 W. H. ST. AUBIN and B. BENTON, Wolverhampton.

Cocks and taps. Dated October 10, 1868.

This chiefly consists in a socket, made of brass or other

metal, having a flange at its front or outer extremity, and
also perforations through the convex sides of the socket

(which is intended to be fixed into the tap hole of the

cask). Into the socket a hollow conical plug is fitted,

which also has perforations. Upon the solid end of the

plug there is a screw, having a square shoulder passing

through a washer, fitting tightly against the end of the

socket, being held there by a nut, which fits upon the

screw or screwed pin. The invention also consists in a

tap having at one end a slot, corresponding with and

fitting the toagues upon the hollow conical plug. Upon

the outer surface of the same end of the top there is a

groove, into which a ring of india-rubber is placed.—

Patent abandoned.

3117 W. R. Lake, Chancery-lane. Electro-plating. (A

Patent abandoned.

3117 W. R. LAKE, Chancery-lane. Electro-plating. (A communication.) Dated October 10, 1868.

This consists, first, in suspending or supporting a mass of the particles of nickel within the solution, so as to present an extended surface, and connecting them with the positive pole of the battery, by means of a platinum or other conductor, not materially affected by the electric current or the solution employed. Second, in lining the whole or a portion of the interior of the vat or vessel which contains the solution with carbon or other suitable conductor of electricity, not materially affected by the electric current or solution, so that the particles of nickel may be placed upon the lining at the bottom of the vat in such a manner as to present the desired surface, the lining of the vat being connected with the positive pole of the battery. Third, in the employment of a plate of metal, carbon, or other conductor, upon which a coat of nickel of sufficient thickness has been deposited as a positive electrode, to be suspended in the ordinary manner, and connected with the positive pole of the battery.—Patent completed.

3118 F. W. Harr, Kingaland-green. Varnishes. Dated

uniform liquid, by a beating machine or whisk. The printed surface of the paper which has been previously dried, is then coated with the albumen thus prepared.

-Patent completed.

3119 N. SMITH, Glasgow. Treating wasts acid liquors Dated October 12, 1868.

The object is the recovery of the valuable products contained in wasts acid liquors, such as are obtained in galvamizing works. When the acid is too weak to be further used, it is saturated with iron, preferably in the form of steel scrap. If it still contains any free acid, as much lime mixed with water as will precipitate the iron is then added. The precipitate is drained, washed, dried, and burned in a suitable furnace, and, if necessary, again washed and dried. The resulting product is oxide of iron.—Patent completed.

2120 C. D. Arriv. Southammton-buildings. W.C. Pro-

aligo C. D. Aber, Southampton-buildings, W.C. Propelling vessels. (A communication). Dated October 12, 1868. This consists in constructing a propeller, composed of shelical or screw blade, fixed upon a shaft, and enclosed by a cylinder, open at the ends, which is fixed to the outer circumference of the screw blade, and, consequently, made to revolve therewith.—Patent completed.

3121 J. Moon, J. H. Donaldson, and E. J. Harris. Oxford-street, W.O. Bedsteads. Dated October 12, 1863. This consists in fixing bedsteads, by means of dovetailed joints or slots, in metal placed either at the sides and ends of bedsteads, or between the ends of bedsteads.—Patent abandoned.

3132 W. MOODIE, Glasgow. Propelling and steering.

ananoned.

3132 W. Moode, Glasgow. Propelling and steering.
Dated October 12, 1868.

This consists, mainly, in mechanism for the propelling or the steering of ships. A main vertical revolving shaft works in a footstep bearing in the keel of the ship, and the journals are in frame bearings above the deck. The shaft carries the two thin and nearly flat rectangular propeller vanes, floats, or blades, one on each side, and exactly opposite to and equi-distant from it, each revolving on its own axis or axial shaft. Lower footstep stud pivots near its centre are parallel, and in a plane with the axis of the main shaft. The pivots are secured to and project up from a two-armed plate or frame-piece, keyed or fixed to the lower end of the shaft, near or close to the lower ends of edges of the floats; the shafts have their lower ends collared or fixed by lateral feathers to them, and the journals work in bearings formed or bushed in the upper armed plate, which is keyed or otherwise secured to the main shaft, close to the extreme upper ends or edges of the vanes or floats, which revolve on their own axes freely between, and with their edges just clear of the carrying arms of their duplex frames, which are strengthened at their outerends by the diagonal stays and main actuating shaft at the centre.—Patent completed.

3123 T. B. Jordan, South Lambeth. Breating minerals.

shaft at the centre.—Patent completed.

3123 T. B. JORDAN, South Lambeth. Breaking minerals.
Dated October 12, 1868.

The breaking machine is a strong cast-iron frame or box containing a hard iron ram, and two wedge-shaped checks, also of hard iron, which have faces curved in horizontal section, and are kept in adjustment by massive wedges against which they are bolted to the frames, by properly arranged adjusting screws. The dressing machine consists of a large hutch or tank of any suitable material for containing water. A sieve of any required mesh is fixed in this tank a few inches below the water surface; over this sieve at one end is a large hopper, from which a narrow adjustable opening, extending the entire width of the sieve, having its mouth on the required level of the surface of the stuff under treatment, furnishes a self-acting adjustment for the depth of sand on the seive bottom.—Patent abandoned.

3124 S. LEONI St. Paul's-street N. Heating and cooking.

abandoned.

3124 S. LEONI, St. Paul's-street, N. Heating and cooking. Dated Uctober 12, 1868.

This relates to cooking by gas, and consists in a portable or fixed frame or stand with a gas ring, and arrangements for the supply of air and gas together; also in a cylinder of fireclay open at the bottom, with a cover of fireclay at the top to act as a reflector of heat. This cover is suspended so as to admit its being lifted off, and let down upon the top of the said cylinder as required, and insome cases the frame is turned on a pivot, so as to remove the cover from the cylinder, and in other cases the cylinder is mounted on wheels, and drawn out from the frame, in order in either case to afford access to the interior of the cylinder, for the purpose of removing the meat or other food therefrom when cooked.—Patent completed.

3125 A. Field and A. W. Tulk, Minories. Show boards

from when cooked.—ratent completed.

3125 A. Field and A. W. Tull, Minories. Show boards
Dated October 12, 1868.

The projecting parts, ribs, or feathers of show boards
are made straight or of a rectangular or curvilinear form
of plain wood, tin, cardboard, or other suitable material,
and the patentee print the required parts of letters, marks,
or devices by means of lithographic stones, wood blocks
type, or equivalent printing surfaces upon material suited
to receive the printed impression, and capable of being
cut into slips and folded, so that the printed slip may be
affixed to the two sides of the feather.—Patent completed.

3126 W. BRAILSFORD and J. GADSBY. Lace. Dated ecober 12, 1868.

3126 W. Brailsford and J. Gadest. Lace. Dated October 12, 1868.

This consists in manufacturing on single tier machines employed in the manufacture of bobbin, net, or twist lace, an embroidered traverse warp net, the pillars of which are each made with one bobbin thread and one warp thread, while the crossings are made with two warp threads, the warp threads the width of the broadth, being made, and, if desired, to traverse the whole width of the machine. When the warp threads arrive at the extremities of the breadths, the left-hand back warp thread is placed in the front, and the right-hand front warp thread is placed in the back.—Patent completed.

understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Property

elastic connection, so that the distance between the centro of the sliding pulley and the fixed end of the elastic con-nection is made to vary as the ends of the carriages vary in distance from the action of the buffers and draw springs. -Patent abandoned.

—Patent abandoned.

3128 T. F. CASHIN, Sheffield. Safety switches and rail joints. Dated October 13, 1803.

This consists, first, in switch levers for working single sets of points on sidings of main lines, branch lines, or for shuntings. Second, in combined levers and appliances for working the points and signals of junctions or stations. Third, in a self-acting arrangement for catch sidings on inclines, and for permitting trains to run behind the points at junctions and stations without deranging the locking gear. Fourth, in a contrivance for forcing the points home close, and crushing any compressible matter that may be between them and the rails when a train is passing over them; and, fifth, in a method for preventing the abutting ends of fish-jointed rails from being depressed below one another, or the connecting bolts from being turned loose.—Patent completed.

3129 W. A. LYITLE, General Post Office, London.

—Patent completed.

3129 W. A. LYTTLE, General Post Office, London.

Electro-telegraphic conductors. Dated October 13, 1868.

This consists in the use of two voltaic batteries or other sources of electricity, one being placed at each end of the wire or other conductor. The positive pole of one voltaic or other battery is connected by means of the conductor with the negative pole of the battery at the opposite end of the system, and the remaining poles of the respective batteries are connected together either by means of a second "return" wire, or by means of the earth,—Patent abandoned. abandoned.

3130 H. C. CLIFTON, Clerkenwell. Ornaments. Dated October 13, 1868.

aliao H. C. CLIFTON, Clerkenwell. Ornaments. Dated October 13, 1863.

This relates to the moulding of ornaments in the material known as "composition." The invention consists, first, in forming such ornaments in a continuous manner by means of machinery arranged as follows:—Upon a long bed is placed a travelling table or board, upon which is laid the composition. At one part of the bed are two upright frames carrying a cylinder or roller, by preference of gun metal or brass, upon the surface of which is carved or engraved the ornaments to be impressed upon the composition. This cylinder receives rotary motion by means of spur wheels from a shaft below the travelling table or board, upon which shaft is a roller pressing against the under side of the table or board, and receiving motion by means of a spur pinion, the shaft of which has either a crank handle turned by hand, or it may be turned by any other source of motive power. The engraved cylinder is carried in sliding blocks in the upright frames, which blocks are capable of being pressed forcibly down to any required extent by means of adjusting screws carried by the framing. The table or beard with the composition laid or spread thereon, is pushed forward so as to enter between the engraved cylinder and the roller beneath, when rotary motion being imparted to the cylinder and roller, as above described, the table or board with the composition. The entire length of the table or board having thus been passed through between the cylinder and roller, it is removed and is replaced by a second table or board with the composition readylaid or spread thereon.—Patent completed.

3131 F. A. Le Mat, New Orleans, U.S.A. Revolters.

completed.

3131 F. A. LE MAT, New Orleans, U.S.A. Revolters.
Dated October 13, 1863.

This relates to those revolving firearms in which, in addition to the ordinary barrel and revolving breech chambers for ball cartridge, there is a central charge chamber and a separate barrel intended for firing grape or duck shot. The invention consists in the combination of the charging of the revolving breech chambers as well as the central chamber is made at the breech. The explosion in both cases is effected by a pin. The hammer head is composed of two parts, articulated together, one of the parts being called the lateral hammer head, which acts upon the ball cartridges in the revolving chamber, and the other part, called the central hammer head, and which acts upon the grape or duck cartridge of the central barrel. The breech of the central barrel carries the pin, and at the same time favours the automatic action of the arm are very strong, owing to the particular arrangement. and at the same time rayours the saltilling or rocking cartridge extractor, owing to the par arm are very strong, owing to the particular arrangement.

—Patent completed.

Patent completed.

3132 G. N. SANDERS, Langham street, W. Lamps.
Dated October 13, 1868.

A glass or globe of peculiar form is employed, consisting of a vertical tube, forming the lower part, which suddenly expands, horizontally, or nearly so, into a wide cylinder, open at the top, the whole being somewhat like an inverted wide bottle. The tube of the glass rests at bottom on a triangle or frame on the gas pipe. On the top of the glass tube, and inside the glass cylinder, a tube or cylinder of tale, or other suitable bad conductor of heat, is placed, which is interposed between the glass tube and the ring burner, so as to provent any air passing from the glass tube to the outside of the burner. The tale also prevents the heat being transmitted from the metal of the burner to the glass. A ring burner, or cetagonal or other angular burner, with a central opening, is employed. The inner upper edge of the burner is chamfered, and the gra a apertures placed on the outer edge, so as to prevent shadows.—Patent abandoned.

3123 W. T. Scog, Vincent-street, S.W. Regulating supply of gas. Dated October 13, 1868.

This relates to previous letters patent (No. 2277), dated September 5, 1866, and consists in numerous improvements in detail in the apparatus and method therein described.—Patent completed.

-Patent completed.

3134 R. Dawson, Plymouth. Gunboats. Dated October 13, 1863.

This consists in constructing gunboats of two separate floating bodies of the same size and shape, and in connecting them togother at a suitable distance asunder, and in forming a cupola of the entire width of the two aforesaid parts, at the midship section thereof, and in fitting the guns, steering wheel, capstan, and propeller all within the cupola, so that the whole working and fighting of the gun boat can be effected within the cupola, and the whole view of the horizon be commanded.—Patent completed.

3123 R Spiece Gower-place W. C. Tokapo jure. Dated

3135 R. Spier, Gower-place, W.C. Tobacco jars. Dated letober 13, 1863.

This consists in adapting a perforated bottom to jars.

The bottom edge of the jar fits into a loose bottom or stand containing a pad, capable of absorbing and holding water, the object and intention being to keep the tobacco from getting too dry.—Patent abandoned.

from getting too dry.—Patent abandoned.

3136 J. WORSTER, Camborwell. Holding sterestype plates.
Dated October 13, 1863.

The blocks on which the stereotype plates are supported whilst impressions are taken therefrom are pressed in three or more parts, each part being of the form of a triangle, or approaching thereto, and being provided with flanges, projections, or catches, rising above the surface of the supporting block or blocks. These flanges, projections, or catches are saitably underent or inclined on their inner sides, so as to hold the stereotype plate. The triangular parts or blocks are formed of various sizes, so as to facilitate the making up of a block to the size of the stereotype plate to be supported.—Patent completed.

3137 W. YATES, Duko-street, S.W. Furnaces. Dated October 13, 1868.

October 13, 1868.

This relates more particularly to puddling, converting, and re-heating furnaces, in which iron and steel are operated upon, and consists in constructing such furnaces or protecting their inner surfaces by a lining, so that they will be better able to resist the great heat to which such furnaces are exposed in metallurgic operations.—Patent completed.

3138 W. R. LAKE, Southampton-buildings, Chancery-lane. Dyeing hair. (A communication.) Dated October 13,

The two substances producing the dyeing effects are nitrate of silver and gallie acid. These substances are prepared for use in the following manner and proportions:

—Nitrate of silver one part, and gum arabic eight parts, dissolved in water and heated to 125deg. Fah., and formed dissolved in water and heated to 125deg. Fah., and formed into a glutinous paste, and gallic acid one part, and gum arabic twelve parts, dissolved in water and formed into a paste. In place of the gum arabic, which is only employed as a vehicle, any suitable glutinous substance, of a similar character, may be used, which will easily dissolve in water, and which possesses sufficient adhesiveness to hold, when dried, the gallic acid and nitrate of silver upon the implement.—Patent completed.

upon the implement.—Patent completed.

3139 R. Ronotham and C. Ezard, Beswick. Top bar frequets. Dated October 14, 1868.

This consists in so arranging the top bar that it may very simply be made to fit accurately to any size of firebar. This is accomplished by making the claw or claws on one side loose, so that they may be moved nearer to, or further from, the others, as the case may require, and when properly adjusted, the loose claw or claws may be fixed in their proper positions by means of a screw.—Patent abandoned.

3140 J. Shanks, Barrhoad, N.B. Water-classit. Dated

3140 J. SHANKS, Barrhead, N.B. Water-closets. Dated October 14, 1868.

3140 J. SHANKS, Barrhead, N.B. Water-closets. Dated October 14, 1868.

This consists in forming a channel round the rim of, and in the same piece with, the earthenware or enamelied iron basin of the closet. The flushing water, entering by an inlet, is made to pass through a hollow rim, and thereby has a whirling motion imparted to it, whilst enough water will run out of it after the tap is closed to ill the basin to the desired height and seal the outlet. This simple contrivance renders any complicated "regulator" quite unnecessary, and the water tap may be arranged to close simultaneously with the main valve, which admits of the simplest possible connections of the working parts. In making the channel in earthenware it is convenient to form it completely round the basin rim at first, and then to insert a nozzle-piece at one side of the inlet, and compel the water to make the complete circuit of the rim. Fine holes are made at various points in the inner and under side of the hollow rim, to admit air, and thereby make sure of the emptying of the channel.—Patent completed.

3141 L. CLOZEL, Parls. Tunning. Dated October 1.

3141 L. CLOZEL, Paris. Tunning. Dated October 1.

This consists in the employment of caustic potash or soda, sulphuret of sodium or hypochlorite of potash or soda, known under the name of cau-de-javelle, in place of the lime for preparing the skins for removing the hair.

—Patent completed.

-Patent completed.

3142 W. R. LAKE, Southampton-buildings. Drilling holes. (A communication). Dated October 14, 1868.

This consists in combining a series of obtuse angled or inclined cranks, in a given space, in such a manner as to operate all of them simultaneously. The obtuse angled or inclined crank consists of an inclined shaft provided at its ends with arms or pins which are parallel to each other, and form, with the shaft, an angle of about 135deg.

-Patent abandoned.

3143 J. H. CARTER, Brighton. Lubricating. Dated Octo-

ber 14, 1863.

This consists, chiefly, in constructing and arranging lubricating apparatus in such a manner that the oil or other liquid is, by the action of pneumatic pressure, kept at a uniform level in a cup or trough connected with a reservoir.—Patent abandoned.

reservoir.—Patent abandoned.

3144 W. R. Lake, Southampton-buildings. Spinning wool. (A communication). Dated October 14, 1868.

This relates to a machine in which the roving is fed at intervals to the twisting mechanism. The latter consists of a revolving tube whose speed is governed according to the amount of twist desired. The yarn or thread, after having been twisted, is taken up by spools placed on spindles, which are supported by rails, which receive an automatic motion by the action of a conical cam mounted on a longitudinally sliding snaft, in such manner that cops of the required form are produced with ease and rapidity.—Patent completed.

3145 J. G. JONES, Blaina, Monmouth. Setting minerals.

rapidity.—Patent completed.

3145 J. G. JONES, Blaina, Monmouth. Getting minerals, Dated October 14, 1868.

This consists in improvements in apparatus employed in getting coal, stone, and minerals. The hole to receive the press-like apparatus is formed by means of a jumping bar, having at its extremity a chisel-like cutting edge of considerably less size than the diameter of the hole required, and some distance up the stem of the tool, which is made tubular; two wings are formed on opposite sides of the stem, and having cutting edges corresponding with portions of the circumference of the hole required. Those wing cutters, following the central cutter, wedge the coal or mineral inwards and into the hole which has been cleared by the leading chisel edge. The tool is turned found between the blows which are struck upon it, as when an ordinary jumping tool is employed. The press-

like apparatus which is inserted into the hole is formed with a series of plungers on each side of it, so that the bearings on the opposite sides of the hole are entirely on the plungers, and no strain but that of the water under pressure comes on the frame of the apparatus, whatever be the form of the hole.—Patent completed.

3146 J. ROBERTSON, Glasgow. Transmitting power. Dated October 14, 1868.

This consists mainly in now or improved modes of

3146 J. ROBERTSON, Glasgow. Transmitting power. Dated October 14, 1863.

This consists, mainly, in new or improved modes of generating and heating or producing fluid currents for generating and heating or producing fluid currents for actuating motive power engines generally: also in new or improved modes of transmitting motive power to, in, and through, or by mechanism or engines constructed so as to have one actuating fluid of each motor introduced, forced, or injected, in the form of a jet or stream through an annular nozzle or other conduit, made so as to draw another or second fluid or fluids into and through the main duct, which is directed and applied so as to actuate the motive power engine or mechanism by its force and expansion. Also in new or improved modes of regulating the flow of the actuating or measured fluids to and from the cylinders of reciprocating motive power engines, fluid meters, or measuring machines, by forming the ports in and through the working surfaces of the cylinder and piston, so as to form also the induction or eduction valve or valves (with or without inducing action, or positively spent currents), and their fluid-tight working surfaces, and by giving the piston an oscillatory motion on its axis in the well known and proper sequential time and relative position to suit that of its own longitudinal reciprocatory motion, instead of the separate slide and other valves usually employed for the like purposes.—Patent completed.

3147 E LEACH, Rochdale. Lattices. Dated October 14

3147 E. LEACH, Rochdale. Lattices. Dated October 14

1863. This consists in making the ends of the metal ribs or bars of which the lattice is composed of improved shapes, and in employing connecting links for enabling the ribs to be readily jointed together in an efficient and economical manner. In one arrangement, both ends of each rib is formed similar to the link of a square chain, and the links are jointed together by connecting links formed of two pieces screwed or riveted together, or by links which, when placed in one position, can be put on and taken off, but when placed in another position, are properly jointed to the links of the chain without any screws or rivets. In another arrangement there are two pins as the end of each rib, and the ribs are connected together by orlinary connecting links held in their places by fastened cross-pieces or retaining bars.—Patent completed.

3148 J. ATKINS, Birmingham. Metallic tubes. Dated october 14, 1868.

October 14, 1868.

The inner or foundation tube is made of sheet iron or other metal by cutting out or porforating the sheet metal before it is made into a tube with any desired ornamental pattern, and the perforated sheet metal is afterwards made into tubing in the ordinary manner. The tube of brass, or other tube with which the foundation tube is to be eased, is then placed upon the said foundation tube and subject the compound tube to a drawing process.—Patent abandoned. doned.

doned.

3149 W. LORDERG, Brunswick-place, N. Treating cotton seeds. Dated October 14, 1868.

This consists in treating cotton seed with sulphuric acid, of a strength and in proportions varying according to circumstances, with agitation, by which the cotton is disintegrated. The disintegration having taken place, the glutinous matter is separated from the seed by the application of water, and the acid removed by an alkaline bath, and the seed rapidly dried by any suitable means. The refuse is employed for manure.—Patent completed.

3150 H. Hupson, Wolverhampton. Stapping trains.

buth, and the seed rapidly dried by any suitable means. The refuse is employed for manure.—Patent completed.

3150 H. Hupson. Wolverhampton. Stopping traiss.
Dated October 14, 1868.

Upon the engine, or other convenient part of the train, a buffer is fixed in any convenient position between the ordinary buffers, the first-named buffer protruding such distance beyond the ordinary buffers as may be desirable. This supplementary buffer is arranged so as to be drawn inwards when it is intended to "back" the train. Each carriage is provided with a horizontal rod, or its equivalent, running the length of the carriage, and protruding beyond the buffer beam at each end thereof. To the ends of this rod are attached dises or buffer heads, and the rod is in a line with the supplementary or first-mentioned buffer placed upon the engine, or other suitable part of the train, and it is so acted upon by springs, or their equivalent, that, on being pushed in either direction, and the pressure being romoved, the rod shall return to its former position. This rod may be connected with the ordinary brakes by gearing, and is so arranged by means of a spring, or its equivalent, that upon a certain pressure acting upon the brakes the rod may pass on, retaining the pressure, but not increasing it—Patent completed.

3151 W. B. Lake, Southampton-buildings. Burning wedgesgriet.

3151 W. R. LAKE, Southampton-buildings. Burning phrocarbons. (A communication). Dated October 14, hudrocarbons.

hydrocarbons. (A communication). Dated October 14, 1868.

This relates to that class of stores ordinarily denominated "petroleum stoves," in which naphtha, gasoline, or other like substance, is employed as fuel for heating and cooking. The invention consists in combining with a petroleum stove an apparatus for generating gas for illuminating purposes, the said apparatus being provided with a receptacle or meter for receiving the gas as it is produced from the naphtha, gasoline, or other fuel; also in attaching a lamp burner to the reservoir containing the said fuel. Second, the invention relates to certain improvements in apparatus for generating and burning gas from naphtha, chiefly for illuminating purposes, and also for heating a nursery lamp. Third, the invention relates to a burner fitted to the bottom of the gas pipe, so that when the gas is lighted the jet of flame will proceed downward, or from below, instead of from the top or side of the burner.—Patent completed.

3162 J. DENNY, Cheltenham. Coffeepots. Dated October 14, 1868.

It is proposed to form the upper and removable division

3153 G. C. GUMPEL. Leicester-square. Locks and latches.

3153 G. C. GUMPEL, Leicester-square. Locks and latches. Dated October 15, 1868.

This consists in the application of pins or sliders of any suitable section, passing through the bolt or bolts, or sliding-piece or pieces, acting on the bolt or bolts, and a fixed piece or bolt, guide, or pieces or guides, in or on which the bolt or bolts, or sliding-piece or pieces, moves or move. The pins or sliders which pass through the bolt or bolts, sliding-piece or pieces, bolt guides, and the bolt shifter, hereinefter described, are cut into such lengths, that when in a given position the divisions of the pins correspond to the divisions or sliding surfaces between the various parts, through which the pins pass, and in other positions only the bolt shifter, hereinefter described, can be moved whilst another part of the pin prevents the bolt from being moved. The pins can be moved into such positions as to enable the bolt to be shifted, either by pressing upon the exposed ends of the pins by the direct application of a key, or by means of intermediate tumblers, which latter are moved by a key.—Patent completed.

ploted.

8154 W. E. Gedde. Wellington-street, W.C. Artificial fuel. Dated October 14, 1868.

This invention consists in using as an agglomerating matter the pure vegetable resin produced by the germinating of the maritime pine, or other trees, or extracted by other means, and with or without any combination or addit ion of other materaglomerating. The effect desired to be produced is the absolute identification of the vegetable resin with the materials to be agglomerated. The single reser vation is the addition of the quantity of cold or boiling water, or of steam useful for preparing the materials, which is brought together, that is to say, the aforesaid slack and dust and the pure vegetable resin.—Patent completed.

pletecl.

515 5 H. A. Bonneyille, Paris. Einstie moulds. (A communication.) Dated October 15, 1868.

This consists in making a mould of such material or composition as to suit it especially to undercut work. Rubber, which has been properly prepared for vulcanization, is taken, and placed over a metallic pattern, and by means of back and front metal mould plates or fixtures, the pattern and rubber compound is securely enclosed, pressure being applied to the external surfaces to force the composition into the undercutting, in this way taking a perfect impression of the pattern. In this condition it is subjected to sufficient degree of heat, in the usual well known manner.—Patent completed

3156 E. Fort and J. Lee. Burnby. Furnace.

3156 E. FORT and J. LEE, Burnby. Furnaces. Dated October 15, 1863

October 15, 1869.
This relates to the construction and arrangement of the bridge of flue-fired boilers, and consists in constructing such bridge of a semicircular form, and extending towards the rear end of the flue, thus forming an arch within the flue, so that the heated cases are confined or throttled between the upper half of the flue and the bridge, and thus partially consuming the smoke; and the arch (which is constructed of firechy blocks, fireclay bricks, fron, or other suitable material), throws off or radiates heat.—Patent abandoned.

heat.—Patent abandoned.

3157 G. C. Attrace and T. Dermer. Wood-street, E.C. Fastening scarces. Dated October 15, 1868.

The buckle or fastener is constructed of any suitable metal, and consists of a plate, in which is formed a slot, one edge of such slot being bent or curved, so as to facilitate the entrance and passage of the band or tongue through the same. One edge of the buckle or fastener is provided with any desired number of curved points or teeth. The buckle or fastener is attached in an oblique or other suitable position to the body or foundation of the seart.—Patent abandoned.

3158 A Robins Great St Helen's E.C. Haten and

scarf.—Patent abandoned.

3158 A. Ronns, Great St. Helen's, E.C. Water and drain pipes. (A communication.) Dated October 15, 1868.

The invention relates to the manufacture of water and drain pipes of oakum, cordage, or other woven fabric or throus material, combined by cementing with pitch, tar, resin, asphalte, or other similar substance, and then coating the same within and without with the same material. In addition thereto a coating of brickdust, sand, coke dust, grit, or other suitable hard particles of matter, is applied as a protection to the surface.—Patent completed.

as a protection to the surface.—Patent completed.

3159 E. Peyton, Birmingham. Springmattresses. Dated October 15, 1868.

The chief object is to improve the mattress known as the "oriental mattress." The invention consists in sloping both sides of the frame down from the two ends, so that they are only two or three inches high at the middle, and for the purpose of supporting the outside spiral springs, of which the mattress is principally formed, as effectually as if they were fastened to the frame commonly in use, but in an unobjectionable manner, at each side of the mattress, an irou, steel, or wood lath is placed, running from head to foot, and attached to the springs, and which, without being fastened, is supported or held at each end by passelag into an aperture or recess formed in the frame, or into a loop of iron, wood, or other suitable material. fastened to the frame, or by some similar contrivance, so that, without being able to come out, it is free to work backwards and forwards, as required by the motion of the springs to which it is fixed.—Patent completed.

3160 T. Gray, Taibach, South Wales. Safety lamps.

backwards and forwards, as required by the motion of
the springs to which it is flaced.—Patent completed.

3160 T. Gray, Taibach, South Wales. Safety lamps.
Dated October 15, 1868.

The "poles," which, as in other safety lamps, support
and keep together the different parts, are hollow for the
purpose of supplying the flame with the necessary oxygen
to support combustion. These hollow or tubular poles
connect the extreme top and bottom of the lamp. At the
bottom the poles are screwed or let into a chamber, in which
the nir, after passing down the poles, circulates, and in
which there is a ring or washer of perforated metal or
gauze, through which the air passes to the flame. From the
flame the beated air and products of combustion ascend
the ordinary glass cylinder, and a metal chimney placed
in the wire gauze cylinder. The ring or washer of gauze
or perforated metal prevents the return up the hollow
poles of the ignited gas, while the lamp is surrounded by,
or is being used to, detect the presence of inflammable
than. A cap prevents dust entering the top of the hollow
poles. Instead of a wire gauze cylinder a close metallic
cylinder may be employed, having in the top a piece of
gauze or perferated metal, to allow the heated air and
products of combustion to issue.—Patent completed.

2141 J. and A. Ball, Nottingham. Lace. Dated Octoin the wire gauze explinder. The ring or washer of gauze or perforated metal prevents the return up the hollow poles of the ignited gas, while the lamp is surrounded by or is being used to, detect the presence of inflammable years. A cap prevents dust entering the top of the hollow poles. Instead of a wire gauze explinder a close metallic cylinder may be employed, having in the top a piece of gauze or perforated metal, to allow the heated in and products of combustion to issue.—Patent completed.

2161 J. and A. BALL, Nottingham. Lace. Dated October 16, 1868.

This consists, first, in manufacturing new or peculiar ground or net in bobbin, net, or twist lace machines, in

which, on each pillar or hole, one or more extra twists to that or those usually given in making ordinary lace or net, is or are placed. The work is "taken up" with the point bars, every motion of the machine using a double set of points on each point bar—that is to say, for instance, in a 10 point machine 20 points are employed, points of various lengths being used as may be required; in an 11 point machine 22 points are employed; in a 12 point machine 24 points are employed; and so on, double the number of points to the actual gauge of the machine being used. Also, in manufacturing on such ground or net spots, spriga, or other devices.—Patent abandoned.

3152 R. M. Wood. Stoke Newington. Type cases, &c. Date: October 15, 1868.

This consists in constructing type cases, work boxes, and other articles having compartments, by making the partitions, which form the compartments, in one piece, without joints, seams, or attachments. A slab or block of wood of the desired length and breadth, and of a thickness suitable for obtaining the desired depth of the compartment, being traced thereon, or on a pattern of paper, or other material laid thereon, aguare, cubical, or otherwise shaped portion of the block or slab of wood, corresponding with and leaving the required cavities, recesses, or openings, to form compartments, are cut away, and necessary portions of the wood left to form the sides, boundaries, or partitions of the said compartments.—Patent completed.

3163 J. A. A. Vacherot, Notting-hill. Beams and girders Dated October 15, 1868.

It is proposed to roll or cast the girder or beam in the form of a single or double trough, the single trough being combined with a vertical web extending longitudinally. In constructing a floor and ceiling according to this invention, two separate and independent sets of beams or girlers are employed for supporting the flooring boards and cellings.—Patent abandoned.

girlers are employed for supporting the flooring boards and cellings.—Patent abandoned.

3164 W. R. Lake, Southampton-buildings, Chancerylane. Gans. (A communication.) Dated October 15, 1868.
This consists in the construction of a gun with a cylinder, formed with any given number of chambers, from which the powder and balls are discharged, which gun is charged with loose ammunition and arranged in such a manner that it is loaded automatically by gravitation, and will discharge in volleys any number of single balls, slugs, or cases of shot. The gun is constructed in such a manner that all the charges of a volley may be discharged simultaneously by the explosion of one cap. The machinery of the gun, which is encased in steel plate, is proof against small arms, and rests upon a pivot, which enables the gunner to direct his fire with ease and precision. The gun is so constructed that it can readily be placed on any kind of carriage, of suitable strength, which may be drawn by horses, or otherwise. It is well adapted to fortifications, in case of an attack by storm, or on vessels, and any place where it may be desired to fire a number of shots in quick succession, as it will discharge 120 volleys per minute with unerring certainty.—Patent completed.

3165 W. R. LAKE, Southampton-buildings Chancery. tne. Breech-loaders. (A communication.) Dated Oc

lane. Breech-loaders. (A communication.) Dated October 15, 1868.

This relates to breech-loading firearms which carry magazines for holding fixed ammunition, and are provided with mechanism for automatically feeding each cartridge in succession, from the magazine into the barrel, into position for firing. In this invention, the magazine is charged through the breech frame, and also in that the feed bar is made detachable from the magazine and is moved entirely away therefrom when the magazine is to be charged, leaving the cartridges free to slide down the magazine from the breech frame. The invention also relates to the construction and arrangement of the hammer mechanism for exploding the cartridge within the barrel,—Patent completed. -Patent completed.

—Patent completed.

3166 T. Vicars and T. Vicars, jun., and J. Smith.
Liverpool. Funaces. Dated October 16, 1868.

This relates to that class of self-feeding smokeless
furnaces wherein a progressive motion is given to the
fuel, and consists, first, in feeding the fuel directly on to
and preferably into and amongst the burning mass, at a
suitable distance above the firebars, instead of from above.
Second, in immersing the lower edges or under sides of
the whole or part of the furnace bars in water, with the
object of making them last longer, and to prevent the
adhesion of slag or clinker. Third, in forming furnace
bars, the lower edges or under sides whereof are immersed
in or dip into water, with cavities or passages, through
which water is allowed to circulate or flow from the
troughs.—Patent completed.

3167 R. Pearce, Swansea. Separation of copper. Dated

3167 R. PEARCE, Swansea. Separation of copper. Dated

3167 R. Pearce, Swansea. Separation of copper. Dated October 16, 1863.

This relates especially to the purification of silver which has been precipitated from any of its salts, such, for example, as sulphate, nitrate, or chloride of copper. The impure silver, or compounds of silver and copper, is placed upon a perforated disc in a boiler. Water is added, together with a small quantity of sulphuric acid, the proportion of the latter necessarily varying with the amount of copper or other impurities present, as will be well understood. Steam, with atmospheric air mineled therewith, is then admitted, by means of any suitable injecting apparatus. Violent chullition cassues, and the copper becomes oxidized, and is dissolved by the sulphuric acid. Should the chullition become too violent, it may be checked by admitting less air. After being boiled in this way for about two hours, the solution of sulphate of copper is drawn off, the silver stirred so as to make it a little more granular, a fresh supply of water, which has been slightly acidulated with sulphuric acid, is added, and the mixture is then boiled for about one heur. The solution is afterwards drawn off, and the silver carefully washed with clean water. The silver, when dry, has only to be melted in crucibles, for fine silver refining in the usual way, by means of lead, being quite unnecessary.—Patent completed.

locomotive passes over the rail the tube gives and allows the rail to take its seat on the bearer.—Patent completed.

3169 W. C. CHUBCH, Derby. Steam engines. Dated October 16, 1868.

3169 W. C. CHURCH, Derby. Steam engines. Dated October 16, 1868.

This relates to a previous patent, dated July 6, 1867 (No. 1974.) The present invention relates, in the first place, to arrangements for removing the pressure of steam from the backs of slide valves, and consists in forming a circular groove in that face of the cap or ring which works against the division plate, so as to intercept or cut off any steam that may leak past the outer portion of the face of the cap or ring, such leakage being taken from the said circular groove, through one or more small holes, to the Inside of the cap or ring, and from thene by small holes at the inner edge of the cap or ring, to the space between the cap or ring and the division plate. The said cap or ring is made with only one cylindrical flange or projection at its outer edge, instead of two (one on each edge), as in the invention above referred to, and the inner surface of the said flange or projection is conical in form. In the second place, to improvements in pistons, described in the specification of patent above referred to, and consists in dispensing with one inner ring, therein described, and in using segmental pieces, straight on one side, to cover the joints of the packing rings acting against the cylinder; also in inserting two packing rings at own k against the inside of the cylinder, and in foreing these two rings apart against the junk ring and piston head by means of an elastic collapsing ring, straight on one side and bevelled on the other. In the third place, to improvements in safety valves and apparatus for preventing damage and accidents in steam boilers. With reference to safety valves, the invention consists in making the outlet for the escaping steam of annular form, and in covering this with an annular or ring valve, held down as required either by a weight or rweights, or by a weighted lever or by springs.—Patent completed.

3170 R. HEAD, Gray-street, W. Stoves and boilers. Dated

3170 R. Hear, Gray-street, W. Stores and boilers. Dated October 16, 1868.

Stoves and boilers are constructed so as to be fitted into a recess of the same or similar form and character to that now usually provided for ordinary open firegrates. First, a stool or support is provided (which is to be placed and stands upon the hearth or bottom of the recess) and on this stool the bottom bars of the grate and also the front bars, like those of an ordinary open fireplace, are carried. This stool or support fits the recess, and is flat on the top with the exception of two broad uprights on its front corners, which sustain the front of the boiler, and the front bars of the stove are between these uprights. Second, the boiler is formed so as to fill up the whole of the recess which is above the stool or support, except a space of a few inches along the top of the boiler, being made deeper at back than in front, so that all along the back it stands upon the flat top of the stool or support, leaving towards the front a space for the fire, extending from side to side of the recess.—Patent completed.

3171 W. E. Newton, Chancery-lane. Surup and sugar

3171 W. E. NEWTON, Chancery-lane. Surup and sugar A communication). Dated October 16, 1868.

from side to side of the recess.—Patent completed.

3171 W. E. Newton, Clancery-lane. Surup and sugar (A communication). Dated October 16, 1868.

First, for the extraction and preparation of the substances to be saccharified, starch is made from grain in the usual and well-known manner, taking care, however, to obtain as much cellulose as possible. In this respect, the process somewhat differs from the usual methods of making sugar syrups from grain or potatock, as that part of the grain which is starch is not only employed, but also other parts, principally the woody fibres of the grain. Having obtained the coarse starch and cellulose, &c., these substances are mixed with warm water, either not acidulated or only slightly acidulated with sulphuric or tartaric acid, in the manner hereinafter described. The mixture above described is put into the boiling vessel, and after hermetically closing the vessel, it is submitted to a high heat of not less than 325deg. Fah. The sweet liquor is drained from the vessel, and as (in any case) there must be always at least traces of acid, it is saturated with carbonate of lime, which is the first but imperfect neutralization. The liquor is then filtered through bag filters, and submitted again with tine bone dust, and sometimes with prismatic sugar, to the action of the great heat in the boiling vessel. It is filtered again and concentrated to 204eg. Beaume cold, and allowed to stand in a receiver at a heat not less than 120deg. Fah. It is then illered, through animal charcoal, and neutralized again at the same time by pure hydrate of soda. This second neutralization renders the liquor entirely free from any acid, and thus favours crystallization. The liquor is holled to about 38deg. Beaume cold, and allowed to crystallize in large moulds. The patentee explains the working rules of the method of using the apparatus hereafter described, which is to be employed for boiling.—Patent completed.

3172 J. Sherman, Whitechapel. Finger rings. Dated

3172 J. SHERMAN, Whitechapel. Finger rings. Dated October 16, 1868.

October 16, 1905.

Finger rings are made in several parts or hoops (preferably three in number), each hoop being set with stones, which, when the several parts of the ring are united together, will form a cluster.—Patent completed.

# APPLICATIONS FOR LETTERS PATENT

Dated April 20, 1869.

1202 L. Goetz, of Leith, Midlothian. An improved pre-gration of materials for cleansing wool, cotton, linen, and other like fibrous substances.

1203 A. Brady, Maryland Point, Stratford, Essex. Pro-ducing pure iron direct from crude iron ore. 1204 F. W. Follows and J. Bate, Manchester. An im-proved apparatus for sweeping carpets, floors, lawns, and other surfaces.

1209 W. E. Gedge, Wellington-street, Strand. An proved water meter. 1210 K. S. Mackenzle, Baronet, Gairloch, Ross. North ritdin. Improvements in fences, railings, hurdles, and

looms

hritsin. Improvements in Johnson 1211 H. Lee, Manchester, Certain improvements in 2018 R. Lee, Manchester, Certain improvements in 2018 G. Green, Aberystwith, Cardiganshire. Improvements in apparatus for separating ores and other certain apparatus for separating ores. ments

ments in apparatus for separating ores and other materials.

1213 W. R. Lake, Southampton-buildings, Chancery-lane. An improved toy.

1214 M. Andrew, Southampton-buildings, Chancery-lane. Improvements in vessels for containing oil or other liquids, and in devices for drawing the contents from the same.

1215 W. R. Lake, Southampton-buildings. Improve ments in lamps.

1216 W. R. Lake, Southampton-unitings. Improvements in lamps.

Dated April 21, 1869.

1216 W. F. Reynolds, Albert-square, Commercial-road East, Middlesex, and J. A. Mays, West-street, Finsbury-circus, City. Improvements in velocipedes, and other vehicles or carriages mounted on running wheels.

1217 W. Holloway, Portland-place North, Lower Clapton, Middlesex. Improvements in apparatus for the manufacture of beverages from cocoa nibs, cocoa powder, paste, or other similar substances.

1218 J., J., and W. Fletcher, Eagle Foundry, Salford. Improvements in lubricating the wheels of velocipedes and other wheels and pulleys.

1219 P. R. Hodge, Adam-street, Adelphi, Westminster. Improvements in the manufacture of cloth or compound fabrics or artificial leather, and in the application of such to certain purposes. to c ertain purposes. 220 E. O. Catrin, Boulevard Bonne Nouvelle, Paris.

1220

1220 E. O. Catrin. Boulevard Bonne Nouvelle, Paris. A novel application of a key to act as a cock at the upper part of bottles, demi-johns, and analogous vessels.

1221 B. Picard, Ivry, Department of the Seine, France. Improvements in towing with sunk chains applicable to the navigation on all rivers, and streams of water, of whatever depth.

1222 J. W. M. Carter, Foyle-street, Londondorry. Im-

whatever depth.
1222 J. W. M'Carter, Foyle-street, Londonderry. Improvements in condensers for steam engines.
1223 T. C. Bull, Weobley, Herefordshire. An improvement in the manufacture of boots or shoes.
1224 M. Henry, Fleet-street, City. An improved mode of obtaining pyro-phosphate of lime.
1225 H. C. Mayer, Craven-street, Westminster. Improvements in velocipedes.
1226 M. Pletts, Newcastle-on-Tyne. Improvements in oil feeders.

1226 M. Pletts, Newcastle-on-Tyne. Improvements in oil feeders. 1227 C. D. Abel, Southampton-buildings, Chancery-lane. A new or improved method of, and materials for, the pre-

A new or improved method of, and materials for, the pre-paration of mural paintings.

1228 C. M. Barker, Kennington Park-road, Surrey. Improvements in steam generators.

1229 W. Johnson, Elms, Sketty, Swansea, Glamorgan-shire. An improved system of communication between railway passengers and the guard and engine driver of a train.

train.

1230 C. E. Brooman, Fleet-street, City, patent agent. Improvements in dressing or finishing fabrics. (A communication).

1231 W. Robinson, Gospel Oak Iron Works, Tipton, Staffordshire. Improvements in the manufacture of thin sheets or plates of steel or of steel and iron.

1232 J. H. A. Bleckmann, Solingen, Prussia. Improvements in firearms.

1233 J. Francis, J. Donaldson, and G. Reavely, Galashiels. Improvements in locking apparatus used for rallway sidings to prevent trucks or other carriages passing out from the sidings.

Dated April 22, 1869.

Dated April 22, 1869. 1234 J. Holding, Manchester. Improvements in looms

SCIENCE AND ART.—A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one conce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelet's Brooches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. The sepamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to Science and ART .- A striking instance of the those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require have it forwarded with perfect safety. [ADVY.]

# MECHANICS' MAGAZINE.

LONDON: FRIDAY, MAY 7, 1869.

## STEAM BOILER EXPLOSIONS.

THERE is no subject upon which we have written more than that of steam boiler explosions. These occurrences are denominated "accidents," but long past ex-perience has taught us that they almost invariably owe their origin to either faulty construction, bad working, or careless and inefficient tending. "Accident" is the convenient term under which steam users often obtain absolution from culpable carelessness, or even wilful and criminal neglect. As matter stand at present, boiler makers can palm off bad boilers on the public, and steam users employ them with the certainty that when they explode with fatal consequences they will, by the help of a coroner and his jury, be publicly absolved from all responsibility, and the event proclaimed to be "accidental." We have said frequently before, and we again repeat, that the causes of explosion are so simple, their results so fatal, and their occurrence so frequent, that it is high time some action was taken to secure common sense investigations into these matters. The Manchester Steam Users' Association has done very much, through their engineer, Mr. L. E. Fletcher, in exposing the fallacy of the present system of investigation. At the last annual general meeting of its members, as well as at the previous one, attention was called to the unsatisfactory character of the inquiries conducted by coroners with regard to fatal boiler explosions, and to the erroneous verdicts returned. It was also shown how important it was that this evil should be corrected, and sound information disseminated in every case, in order to check the loss of life and suffering at present recurring week by week, and at the same time render unnecessary any Governmental action, which might prove an interference with the free-dom of the steam user. With this view, resolutions—which have appeared in our columns—were passed at both of those mectings, requesting the committee to take the necessary steps to secure these investigations being rendered more satisfactory, so that the truth might be fully arrived at and plainly spoken in every case. In order to place the matter prominently before the public, a paper upon the subject was read at the last meeting of the British Association. Following this, at the annual general meeting of the Steam Users' Association, held on March 9 last, it was proposed that the attention of the Government should now be drawn to the subject, and that a deputation should wait upon the Home Secretary with a memorial.

Thus far, this useful Association had pro-posed. Now came the time to act; and we find that no time was lost in carrying out the proposition. At the following meeting of the Executive Committee, a memorial was submitted for approval, discussed, and adopted. Mr. Thomas Bazley, M.P. for Manchester was at once communicated with, and his assistance in the matter requested; and through his good offices, a deputation of the Association had an interview with Mr. Bruce, the Secretary of State for the Home Department, on Friday, April 16. A sudden and severe attack of illness prevented Mr. Fairbairn, the President of the Association, accompanying the deputation. It consisted of three of the vice-presidents, Mr. Thomas Bazley, M.P., Manchester; Mr. Hugh Mason,

M.P., of Bolton, Corresponding Member, and Mr. L. E. Fletcher, Chief Engineer. Mr. Bazley introduced the deputation to the Home Secretary, and briefly called at-tention to the serious loss of life and suffering entailed by steam boiler explosions. He pointed out that this was preventible, and explained that it was the wish of the memorialists that coroners should be empowered and instructed to command the attendance of eminent engineers to give evidence, when conducting enquiries, in consequence of these sad disasters, so that light might be thrown on the subject, and greater care induced: by which means, it was thought that the loss of life and property now occurring would be much lessened, if not altogether prevented. Mr. Bazley concluded by presenting Mr. Bruce with the memorial, which we shall now proceed to notice.

We have often had occasion to observe that it is entirely in the hands of steam users whether they will, by the exercise of common sense and ordinary discretion, save themselves from Government interference and control. or whether, by persistently pursuing a short-sighted and danger-fraught policy, they will continue to court that supervision which they would be the first to most strenuously resist. Nor would we wish to see such a system established. Nor does the Steam Users' Association desire this. On the contrary, the object the memorialists have in view is not to promote a system of Governmental periodical boiler inspection, to which manufacturers entertain a strong feeling of repugnance, and which the Association was originally founded to prevent. But the object is to so improve coroners' inquiries with regard to boiler explosions, that sound views with regard to the causes of these disasters may be disseminated, and all mystery with regard to them dispelled. Boiler explosions would be prevented, and further Governmental interference would be rendered unnecessary, if only faithful investigation and plain speaking were made compulsory. And the way in which this is to be accomplished is clearly set forth in the memorial. That important set forth in the memorial. That important document first points out the constant loss of life and the suffering arising from steam boiler explosions. At the present time, nearly 50 explosions occur on an average every year, explosions occur on an average every year, killing from 60 to 70 persons, and injuring as many others. Many of the persons killed and injured are breadwinners, so that not only do they suffer, but a great many others are rendered more or less destitute. The number of persons killed every year by boiler explosions exceeds the number of passengers killed on all the railways throughout the United Kingdom. From the return published by the Board of Trade, it appears that during the last six years 123 passengers were killed while during the same period 390 persons were killed by boiler explosions, the annual average of lives lost being from 20 to 21 in the case of railway passengers, and of 65 in consequence of boiler explosions. Thus it will be seen that for every passenger who loses his life by railway travelling, three persons are killed by boiler explosions.

Such are the results. Now as to the cause and this, as shown by the memorial, is summed up in one short word-neglect. system of voluntary periodical boiler inspec-tion carried out by the Association for the last fourteen years has proved fully adequate to the prevention of explosions; not a single boiler ever guaranteed has exploded. The constant investigations of boiler explosions have shown that much unnecessary mystery has been attached to the subject of steam boiler explosions, and that they all arise from the simplest causes, and could readily be prevented. As a rule, boilers burst simply because they are bad. Bad either from

follow that if people will have no care for themselves, no one ought to care for them. But the suffering does not always fall on the careless ones. Death is dealt around amongst the innocent, whilst the guilty are generally absolved, even from blame. It is for and on behalf of the real sufferers that the Association interferes, and by the memorial shows coroners' investigations, with regard to steam boiler explosions, to be incomplete, and the verdicts delusive. It is not as an institution that the coroner's inquest is condemned, but it is the manner in which it is practically carried out to which the strictures in the The next point is, how this be met. The plan recommemorial refer. difficulty is to be met. The plan recom-mended for adoption in the memorial is simply that every coroner should be both empowered and instructed, when conducting an inquiry consequent on a fatal steam boiler explosion, to avail himself of the assistance of two competent engineers, having no connection with the works at which the explosion occurred. These engineers are to visit the scene of the catastrophe, investigate the cause of the explosion, and report to the coroner thereon, their reports—which may be either joint or several, as most convenient -to be accompanied with explanatory scaled drawings, showing the original construction of the boiler, and, as far as possible, the lines of rent, as well as the direction in which the fragments were thrown, and the distances at which they fell. The engineers to attend the inquest, and assist the coroner in his examination of witnesses, as well as to give evi-Further, dence themselves before the jury. in order to secure to the public the full advantage of the investigation, the engineers' reports, with the drawings, to be printed and deposited in the Patent Office, and to lie there for inspection and purchase, as in the case of specifications of inventions. Also copies of these reports to be forwarded to the members of both Houses of Parliament, as in the case of reports on railway accidents.

Such a course of procedure would primarily result in the accumulation of a mass of very valuable information. But beyond this-and what is of the highest importance the responsibility of every steam boiler explosion would be brought home to the right party. This would render any further Governmental action unnecessary, and very shortly put an end to steam boiler explosions, simply by the force of truthful investigation and plain speaking. The fact is not lost sight of that many coroners have already the power—of which, in some cases, they avail themselves—of remunerating competent scientific witnesses, and which proves of considerable public service. But such is not the case in every instance, and coroners to whom the plan proposed in the memorial has been mentioned, have stated that it would prove of considerable assistance to them in conducting their investigations on such technical subjects as boiler explosions, and that they should be glad to see it brought into operation.

In his reply to the memorial, Mr. Bruce appeared to fear that there might be some partiality in affording to boiler attendants a Governmental investigation on the occurrence of fatal disasters, without extending that protection to railway passengers and colliery workers. But it should be remembered that the very protection now sought for boiler attendants is already enjoyed by railway passengers and colliery workers, while the boiler attendant is left unbefriended, so that the partiality anticipated already exists to the neglect of the poor stoker, while the tendency of the Association's proposition would be, not to create a partiality, but to remove one already existing. The plan recommended is, in fact, simply an extension to boiler at-Ashton-under-Lyne; and Mr. John Penn, because they are bad. Bad either from tendants of the privileges enjoyed by railway original malconstruction, or bad from the caster, M.P., Wigan; and Mr. Thos. Schofield, Manchester, members of the Executive Committee; as well as of Mr. John Hick, and the preventive simply care. It would sent down to make an investigation, and

report to the Board of Trade thereon, his report being presented to the members of both Houses of Parliament, and open to the purchase of the public; while, in addition, he attends the coroner's inquest, and assists in the examination of witnesses. In the event of a colliery explosion, a Government mining inspector is present at the inquest, and assists the coroner in conducting his inquiry; while an annual return of colliery explosions is published. In the event, how ever, of a boiler explosion, though the subject is one of a technical character, and on which a good deal of misapprehension exists, while questions arise with regard to it which may fairly be considered as beyond the province of what is technically termed "common knowledge"; yet boiler attendants are left without the protection of a satisfactory investigation of the cause of the catastrophe, and evidence from incompetent parties, or from those interested in suppressing the facts, is accepted, and, consequently, as so often stated, the truth is seldom arrived at and seldom spoken.

It will be seen, from what we have stated, that some action is needed to redress the present inequality, and afford to boiler attendants the privilege of as unbiassed an investigation as is now secured by the Crown to colliery workers and railway passengers. The initial movement in this action is now being taken by the Manchester Steam Users' Association, and should they succeed in bringing the measure they propose into operation, they will richly deserve the thanks boiler attendants, boiler owners, and boiler makers. They will deserve the thanks of boiler attendants for saving the lives of some sixty or seventy of their number every year, many of whom are breadwinners, and by thus preventing a vast amount of suffering, not of themselves only but also of their families. They will deserve the thanks of boiler owners and boiler makers for preserving them from a system of Governmental periodical inspection, to which sooner or later they would otherwise inevitably subject themselves, and which could not fail be harassing, and to limit progress. They will also deserve the thanks of the public for the additional security they will have imparted to life and property. We give them our cordial support in the matter, and our best wishes for their success.

## NEW USES FOR PAPER.

NEW branch of industry has just been introduced to our notice. We have for some time been familiar with various novel applications of paper. We have good paper shirt collars and wristbands, paper waist-coats (up to this time of villanous appearance), paper shirt fronts or dickeys (just as ill-looking), and we have seen bonnets, which, however, no female denizen of Whitechapel would think of putting upon her head. But now the uses of paper are very much extended by a patent process of M. Pavy. The paper made by this process is of a peculiar kind. It very much resembles that used by the Japanese for pocket handkerchiefs, and is susceptible of the same application. The patentee calls it "felted," and to a certain extent the term is appropriate. Both animal and vegetable materials are employed in its production. Among the vegetables we find some not hitherto much employed in the manufacture of paper, New Zealand flax, jute, plants of the mallow, and the ordinary fibres, flax, hemp, and cotton. The animal matters used are wool, silk, skins, and another material, which is certainly a novelty in paper-making. These various matters are reduced to pulp and bleached, and then "felted" in appropriate machinery, which is, no doubt, the same as is used in ordinary paper-making. It will easily be understood that the mixture of such materials as

we have named gives a paper of extraordinary pliancy, flexibility, and strength. It can, indeed, be sewn together with as much ease, and makes as strong a seam as the woven fabrics it is intended to replace. The uses to which this paper can be put are innumerable. We may mention a few of the articles we have seen at the office of Messrs. Roberts and Thorne, 82, Gracechurch-street, City. First, petticoats, which no girl of the period could resist. These may be printed exactly like the skirts now so fashionable, or they may be white, and have open work stamped out in patterns, which scarcely any amount of labour with scissors and needle could imitate. The marvel is that they can be sold retail for sixpence each—little more than the cost of washing a petticoat. We have next bed furniture, of imitation cretonnes and chintzes. These are printed with patterns of great beauty, and a set of curtains will only cost five shillings. We have also quilts, which, besides being excellent nonconductors of heat, have a very ornamental appearance. White day covers for beds are made with embossed patterns and equally cheap. White tablecloths, stamped with patterns in remarkably good taste, will, we are sure, soon ornament many a dinner table, and serve to light the fires the day after the party, unless the host be of an economical turn and resells them to the papermaker. But the material is also applied to articles of a more substantial character. Very good imitation leather is formed of it, and furniture covering, and even shoes, may be made. The last can be made impermeable to wet by the introduction of oils and india-rubber. We have said enough to show that a material is produced which will probably have considerable influence on some of our staple industries. Paper collars, it may well be sup posed, have already had a sensible influence on the linen trade, and the further extensive substitution of paper for woven fabrics mus produce still greater changes.

## THE "HERCULES."

IN the Mechanics' Magazine for April 23, a letter appeared A a letter appeared, over the signature of "Detector," in which the writer indulged in a tilt, with full steam on, at the engines of the "Hercules," and their performances. In our present issue, at page 236 appears another letter from the same writer, referring to the same vessel, and upon which we propose to say a few words. As regards the communication itself, we could wish it were written more in the spirit of true scientific discussion and criticism, and less in the captious fault-finding Moreover, we should like to have found some suggestions for improving the points complained against. Any one can vote an R.A. painting a daub, but it is not every one who can produce even a daub himself. However, we let this pass, and take the letter as it stands. Our correspondent "Detector appears to entertain somewhat exaggerated notions respecting the bow wave thrown up by the " Hercules." Not only does he believe it capable of rendering the bow chasers useless notwithstanding the fact that they are about 14ft. above the ship's load water-line-but he gives it credit for maintaining this formidable height in its passage along a length of more than 100ft. of the ship's side, and then swamping the central battery by rushing in at the wing or recessed ports. There can be no doubt, and we do not wish for a moment to deny the fact, that the plough bow, valuable as it is for ramming, does cause a bow wave, and that in steaming against a head sea, at a rapid rate, the main-deck bow chasers of this ship might be, at times, rendered useless. This probability, has, we believe, been foreseen; and the "Hercules'

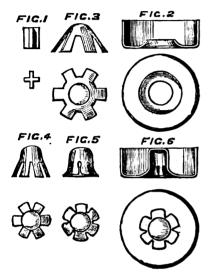

for use in chasing. But while this is true when the circumstances are so bad as we have imagined them to be, it is also true that in comparatively smooth water, even when steaming at full speed, there is no difficulty in fighting the main-deck guns. This statement is supported by reference to the six hours' trial outside the Isle of Wight, when the bow wave never rose within several feet of the bow port sills. In a general action, which is necessarily fought at low speed, or at comparative rest, the bow wave would not

With respect to the coal supply, we also think there is some misapprehension in the mind of our correspondent. It was shown by Mr. Reed, at the meeting of the Institution of Naval Architects, that by means of the increased weight of engines given to the "Hercules," and put into superheaters, surface condensers, &c., her 600 tons of coal will enable her to steam farther than any other ironclad, except the "Warrior," but little less distance than even that ship. There is small probability, we think, of the "Hercules" "being chased by a much swifter ship," since she is the fastest and strongest ironclad yet afloat. As to handiness, also, it is a matter of fact that the "Hercules" has been pronounced to be far superior not only to our other ironclads, but to nearly all war ships, by those who have witnessed her performances at sea. With respect to her cost, we can only go as far as the published returns carry us, and according to the figures there given the "Hercules" is by no means the "most expensive vessel ever constructed"; while we most strongly object to her services being limited, as our correspondent does limit them, "to coast and harbour defence." Her trials at sea prove her to be one of the most, if not the most, efficient sea-going ironclads we possess, both under steam and under canvas. We are at all times desirous of inserting fair and candid criticism upon the ships of the navy, because of the good which we know results from such criticism; but we cannot see what good is to result from imputing to important ships of our own navy—ships which are undoubtedly the best in the world -defects which do not exist. We trust "Detector" and other would-be critics will learn in future to distinguish between mere cavilling and a fair open discussion of facts. True, it is an Englishman's privilege to grumble, but it is only just to those with whose works they find fault that the grumble should have a substantial basis, and not beas in the present instance-directed against shadows.

# MANUFACTURE OF CAPS AND CARTRIDGES.

No. VI.

MOST of our readers are probably acquainted with what are termed "saloon firearms," adapted for indoor practice. They appear to have owed their introduction to the days of duelling, when it was necessary for any well-known "shot" to keep his "hand in" by practising in a large drawing room or saloon, when he had nothing to occupy him in the field. The caps manufactured at the establishment of M. Gevelot, and intended for the cartridge of firearms of this description, are filled in nearly the same manner as that already described for those destined for a more warlike purpose. The cartridges to which we now allude carry simply their priming and a small bullet not much larger than buck shot. Over the cavity of these caps, after the introduction of the priming, and while they are still under manipulation, is placed a small piece of paper. They are is placed a small piece of paper. then submitted to the action of the punch. which presses the paper down upon the powder, while the bullet is subsequently fixed has upper deck guns which could be fought in by the hand. The caps which are intended all weathers, and are more particularly intended for percussion guns are packed in boxes and by the hand. The caps which are intended sold at the rate of sixpence a-piece. Those which are to be attached to cartridges are despatched to the workshops, where the different parts composing the cartridge are severally put together. The cartridge is short and broad. Those used by the infantry are 1.84in. in length, and those manufactured for the carbines of the Chasseurs de Vincennes have a length of 1.56in.; the diameter of both descriptions is 0.68in. The percussion or detonation is effected by a point, which a steel spring draws back directly the blow has been given. In order that the fulminating powder should explode under the shock which is received upon the copper of the cartridge, a small piece of brass, called an "anvil," is placed inside. This anvil, which has four arms at right angles to one another, is represented upon a scale of full size in plan and elevation in fig. 1.

We shall now pass on to the description of the operations by which the various pieces composing the entire cartridge are connected together, so as to render that dangerous little missile complete. The bottom piece, which is of brass, is cut by machinery out of strips of that metal of the thickness required, and each machine can turn out 160,000 of them. force with which this cutting-or, rather, punching—out is effected hardens the metal to such an extent, and renders it so exceedingly brittle, that in that condition it could not be further used. They are, therefore, annealed, and a red heat restores the brass to its original degree of malleability and elasticity. Those of our readers who have visited the Royal Mint are aware that precisely the same thing takes place in the coining of sovereigns. After the little discs of gold have been stamped out of the strip or ribbon of that metal, they are immediately packed together in an iron dish or tray, covered with clay, and subjected to a strong heat in a furnace. This annealing process is absolutely necessary to soften them, in order that they may be enabled to properly receive the impression of the die.

Although this process restores the brass to its normal state, it blackens the surface so much that it has to be cleaned. During this much that it has to be cleaned. During this operation the brass is covered with a thin film of pure copper. This is accomplished by dipping the brass bottoms or end pieces of the cartridge into a bath of sulphuric acid, in which some sulphate of copper has been directly desired. The code are pleased in a backet. dissolved. The ends are placed in a basket of wood or gutta-percha, and in order to stimulate the electro-chemical action, a few small fragments of iron are thrown upon the the basket. After agitating basket for a short time, it is withdrawn, and the "ends" appear glistening with the rosy tint of fresh copper. The basket is washed in water, to remove all traces of the acid, the ends are dried in sawdust, passed through a completely formed. sieve, then placed in an iron barrel rotating upon its axis, for the purpose of being polished, by this little machine.

and finally transferred to another workshop to undergo the next process. This consists in their being pierced through the centre, and a small piece taken out therefrom, which is carefully preserved, as its sale suffices to pay the cost of the piercing. By the same blow, a slight circular depression is made round the hole, and upon the inside the lips of the aperture are turned up, and form a kind of rim, which serves to retain the little chamber that is subsequently placed therein. The "ends" in this stage are represented in fig. 2.

Next comes the fixing of the chamber, which is also accomplished by the blow of a die which forces it into the opening already made in the cartridge end, and beats out the wings of the chamber around the depression formed in the "end." At the same time, a small drill rises up out of a slit in the anvil upon which the striking occurs, and pierces a hole in the bottom of the chamber, thus forming a communication between the interior and exterior of the cartridge end, without which the explosion of the charge could not take place. In figs. 3, 4, and 5 are represented in plan and section the changes that take place in the shape of the chamber during the action of the die and its insertion in the cartridge end. Fig. 6 shows the cartridge end comend. Fig. 6 shows the chamber, and ready pletely furnished with the chamber, and ready the succeeding operation. While the for the succeeding operation. While the preparation of the cartridge ends, as just described, is being carried on in one work-shop, that of the bodies of the cartridge, or cases, are being actively executed in other portions of the premises. The body or case of the war cartridge is different from that of its more peaceful relation, the sporting cartridge. In the latter, it consists simply of paper glued together round a mandril; but in the former it is strengthened by the addition of a coating of brass, so thin that it partakes of the nature of tinsel. The sheet of metal, having been first flattened out, is annealed, to bestow upon it a temper that would permit of its being easily rolled into the cylindrical form required, and all that do not "take kindly" to the operation, are too thick, and rejected accordingly. To obviate the constant occurrence of this delay and inconvenience, the sheets are weighed in the roll as they arrive from the rolling mill. Each piece suffices to make eleven sockets, and should not exceed in weight 238 grains. A margin of fifteen grains is allowed either in excess or deficiency, but any roll that passes those limits is summarily rejected.

The first step consists in laying out upon a slate tablet the piece of paper intended to form the exterior covering of the thin sheet of brass tinsel, and giving it a coating of size. In the meantime, the metal has been bent round upon a mandril, so as to approximate to the required shape, and the two envelopes of metal and paper are then rolled round it together. Before these cases are con-sidered properly finished, they are tested by a gauge of the exact size of the bore of the guns for which the cartridges are intended. f the cases do not fit, it is an indication that they have been badly manipulated, and they are either remade or thrown aside. summer time, these tubes or cases are dried in the sun, and during winter in drying rooms maintained at a temperature of about 105deg. Fah. A practised hand can turn out several thousands of these tubes in a day, and can earn four shillings a day. A very ingenious machine has been invented for the purpose of manufacturing these tubes, by M. Champelle, the manager of the premises situated in the Rue Amelot. The girl engaged in the work first sizes the paper, then places the brass sheet and the paper within the action of a pair of small cylinders, and the case emerges completely formed. As many as 40,000 of the cases can be manufactured in a single day

THE METEOROLOGICAL SOCIETY.

MEETING of the Meteorological So-A ciety was held, on the evening of April 21, at the Institution of Civil Engineers. Mr. James Glaisher, the president, gineers. Mr. James Glaisher, the president, was in the chair, and there was about the usual attendance of members, including Colonel Strange, Drs. Tripe, Brooks, and Mann, Messrs. Doggett, Perigal, Symons, Eaton, Dines, Strachan, Casella, Pastorelli, &c. Dr. Mann read a short paper on earthquakes, in which he repudiated the popular idea that they are connected with meteorological phenomena. Colonel Strange contended that not only was there no evidence of such relation, but that there was no physical phenomena. sical theory to support the notion. Now that attention is directed to the absurdity of the thing, no doubt there will be much less nonsense written about the weather during earthquakes. Mr. Dines read a paper on the fall of rain in reference to the age of the He had worked with two series of observations, one made at Cobham and the other at Chiswick, extending over forty years each. The conclusion at which he arrived was that the fall of rain did not appear to be in any way governed by lunar influence. This paper was followed by a more elaborate one on the same subject, by the President, who had examined fifty-four years' observations made at Greenwich. He found that the tions made at Greenwich. He found that the greatest amount of rain fell on or about the tenth day of the moon's age. The amount is not of such magnitude, it seems to us, as to warrant the conclusion that it is the result of lunar influence. If forty years furnish no evidence, fifty-four years a shaky evidence, probably a longer series would only yield evidence equally doubtful; therefore, the practical conclusion seems to be that lunar influence on rainfall is nil.

In discussion, Colonel Strange and Mr. Doggett both expressed very high opinions upon the merits of these two papers, but were understood to assert that there was no physical reason for imagining that the age of the moon could have anything to do with the production of rain. Colonel Strange also pointed out that rain is often dependent upon local conditions, as at Cherrypongee, in India, where 640 inches of rain have been known to fall in one year; and our own Cumberland Hills furnish another example, for at Seathwaite 180in. is the annual fall. Besides, the wind and the temperature are the immediate active agents in the production of rain; hence, whatever influence the moon might have on rainfall, it ought also to have on the regulation of the winds, the temperature, The results and the atmospheric pressure. of an immense expenditure of time and trouble over these investigations only prove their futility. Henceforth, let them be considered as the vigia of meteorological research.

Mr. Smyth, of Bainbridge, Ireland, read an account of his investigation into the mysterious agent ozone, describing his methods and results. He advocates the use of an aspirator. With his apparatus he has found the ozone in the air at all times a constant quantity. This announcement created much surprise, and Mr. Smyth was, in consequence subjected to a species of cross-examination, but he was quite ready with explanation upon all points. Mr. Glaisher stated that the value of ozone tests was undeniable. the cholera season of 1854, he organized an extensive series of observations on ozone throughout the metropolis. When he came to compare these observations with the returns of mortality for the respective districts, this was the remarkable result:—Where the test papers remained white there were no deaths from cholera; where the papers were browned, cholera was active, and its victims numerous. Mr. Symons urged that Mr. Smyth's investigation ought to be carried on at other places, and verified before his results were adopted by meteorologists. Mr.

Casella, in a fluent speech, dwelt upon the from the retarding medium. This produces value of self-acting apparatus for recording ozone, and upon the importance of uniformity in the methods of observing, or as regards the preparation of the test paper at least.

It is a pity that a larger gathering of persons interested in meteorology cannot be got together, especially when discussions of so instructive a kind as took place at this meeting occur. The annual general meeting will take place on June 16.

## THE ROYAL INSTITUTION.

PROFESSOR R. GRANT, F.R.S., delivered his fourth lecture on "Stellar Astronomy," on Tuesday, April 27, at the Royal Institution. He spoke chiefly of the brilliancy of the light emitted by the stars, and told how an attempt was made by the early astronomers to learn the distances of the stars by measuring the intensity of their light, before astronomical appliances were sufficiently perfect to measure their distances by parallax. The intensity of the light of the planet Saturn, as compared with the light of our sun, was first measured, and then the light of Saturn was compared with the light from the stars. It was then assumed that the stars were nearly equal in size and splendour, and it was found that the sun would have to be removed to 220,000 times its present distance to look like a bright star. The sent distance to look like a bright star. distances of different stars thus computed were afterwards, when measurements by parallax were perfected, found to be, for the most part, too small; hence it was discovered that many of the stars are larger than our sun, and superior to it in brilliancy, whilst

other stars, again, are smaller than the sun.

Professor Tyndall, LL.D., in his fourth
lecture on "Light," delivered on Thursday, April 29, explained why the theory of Newton and other early philosophers, that light consists of small particles emitted with great velocity from the luminous body, had to be abandoned, and he told how the wave theory of Thomas Young and Augustin Fresnel came finally to be adopted. The wave theory assumes the existence of a medium of extreme tenuity and almost infinite elasticity, which fills all space, and bathes the atoms of all material substances. The particles of luminous bodies are believed to be in a state of intense vibration, throwing the surrounding ether into waves, which travel through space, pass through the humours and lenses of the eye, and beat against the retina, in a manner as truly mechanical as the impact of waves upon the sea-shore. The properties of this wonderful ether were minutely described by the lecturer, who said that the reflection of ether waves obeys the law established in the case of light. The angle of incidence is demonstrably equal to the angle of reflection. To account for refraction, for the sake of simplicity, take a portion of a circular wave emitted by the sun or some other distant body. A short portion of such a wave would be straight. Suppose it to impinge from air upon a plate of glass, the wave being in the first instance parallel to the surface of the glass. Such a wave would go through the glass without change of direction. But as the velocity in glass is still less than the velocity in air, the wave would be retarded on passing into the denser medium. But suppose the wave, before impact, to be oblique to the surface of the glass; that end of the wave which first reaches the glass will be first retarded, the other portions being held back in succession. This retardation of one end of the wave causes it to swing round; so that when the wave has fully entered the glass its course is oblique to its first direction. It is refracted. If the glass into which the wave enters be a plate with parallel surfaces, the portion of the wave which reached the upper

a second swinging round of the wave, by which its original direction is restored. simple way, the wave theory accounts for refraction. The convergence or divergence of beams of light by lenses is immediately deduced from the fact that the different points of the ether wave reach the lens, and are retarded by the lens in succession. The density of the ether is greater in liquids and solids than in gases, and greater in gases than in vacuo. A compressing force seems to be exerted on the ether by the molecules of these bodies. Now, if the elasticity of the ether increased in the same proportion as its density, the one would neutralize the other, and we should have no retardation of the velocity of light. The diminished velocity in highly refracting bodies is accounted for by assuming that in such bodies, the elasticity in relation to the density is less than in vacuo. The observed phenomena immediately flow from this assumption. The case is precisely similar to that of sound in a gas or vapour, which does not obey the law of Mariotte. The elasticity of such a gas or vapour, when compressed, increases less rapidly than the density; hence the diminished velocity of the

Professor Tyndall next gave evidence that colour is only a phenomenon of wave-length, there being no difference between red and blue, except that the waves of the former are longer than those of the latter. To show that white light is a compound of many colours, he took a brilliant beam of light from a small round hole in the electric lamp, then passed it through a lens and prism, so that a small impure spectrum fell upon the screen. Between the prism and the screen he then placed another lens, and not only did the spectrum disappear, but a well-defined white luminous image of the carbon points was seen. Then he inserted the thin edge of a small prism a little way into the beam, and thus, by refraction, obtained two images of the carbon points upon the screen, one green and the other red—complementary colours. When the little prism was removed, the colours and images blended, to produce, as before, one brilliant uncoloured image.

On Friday, April 30, Mr. Robert Scott, of the Meteorological Office, gave a lecture at the Royal Institution upon the Meteorological Department of the Board of Trade. exhibited some of the self-recording instruments at work, and gave a history of the changes in the department since the death of Admiral Fitzroy. The system of storm signals now on trial differs from those of former times, in that now no attempt is made to foretel coming storms, but only to inform mariners, by telegraph, of the position and direction of storms at other parts of the direction of storms at other parts of the coast, leaving them to form their own con-clusions. The signalling apparatus to convey this information, now on trial at Blackwall, Liverpool, and North Shields, consists of a tall post, with two arms at the top, worked semaphore fashion, and so arranged as to tell the position, direction, and force of wind of an existing storm. In one respect, the apparatus is not so good as that employed by the late Admiral Fitzroy, because the new signals are not equally visible from all points of the compass. As yet, the records in the Meteorological Office have elicited few new facts about the weather, though it has been ascertained that some storms are exactly repeated after a long interval. The observa-tions tend to confirm Buys Ballot's law:— "Stand with your back to the wind and the barometer will be lower on your left hand than on your right." North-west winds are, however, an exception to this law.

ELECTRICITY AND TELEGRAPHY. HE manufacture of the French Atlantic cable

at the works at Wharf-road, and of the total length of the cable, one section, that from St. Pierre to Boston, has been completed at Mr. W. T. Henley's works, at North Woolwich. The larger section, from Brest to St. Pierre, now making at the Telegraph Construction Company's works at Greenwich, has made such rapid progress that there is no doubt but that it will all be completed to time. The total length of both sections manufactured to last week was about 3,350 miles, and of this length nearly 2,700 miles had been shipped. Three vessels are now receiving cable, the "Great Eastern " (with over 2,100 miles on board of main deep sea cable), the "Scanderia" (with 450 miles of the United States section), and the "William Cary" (with only, as yet, a short length). It is anticipated that the "Great Eastern" will leave Sheerness about the second week in June, but before that time we hope to place before our readers some further interesting details of this truly great enterprise.

Immediately after the completion of the core for the French Atlantic cable, at the Gutta-Percha Works, the conductor for the British Indian line was commenced to be insulated, and before the "Great Eastern" can leave, the machines Greenwich will be in full work manufacturing this cable, which will be a few miles longer than the French Atlantic cable. This cable be in two sections, the one from Suez to Aden, and the other from Aden to Bombay—a total length of 3,600 miles. The two sections differ from each other in the size of core and in external protection, but on the commencement of the work we shall be enabled to give some particulars.

The breaking up of the ice in the Baltic has enabled Mr. Henley to proceed with the work of laying the second and longer section of his Baltic This section, from the island of Bornholme to Liban, in Russia, was interrupted by the formation of the ice last year, and now the vessel engaged has commenced to lay the cable, and in our next its completion may in all probability be announced. At his works at North Woolwich, Mr. Henley is now manufacturing two cables, the one for the Norwegian government, and the other for the new line from Peterhead, in Scotland, to Norway. The conductor in this cable is insulated with Hooper's material.

The South Lowestoft cable was lately broken at sea, and owing to the absence of the company's repairing ship, the interruption was longer than usual; however, owing to there being a second cable between the same points, communication carried on as usual.

A new arrangement of a battery has been intro-duced by M. Guyot. He fills an ordinary porous vessel with finely powdered iron ore; this vessel is placed in an outer vessel containing a concentrated solution of common salt, having a cylinder of gas retort carbon as the second element. are unable to give any information as to its working, but the cheapness of the battery is manifest,

It had been for some time confidently expected that the Government would have brought in their Money Bill, for the purchase of the electric telegraphs of the country, at such an early date in the session as would have allowed the transfer of the telegraph system to the Post Office to have been completed by July 1; at present, the Bill has not been brought in, and it can now hardly be hoped that the Bill can be introduced in sufficient time to allow the transfer to take place at the expected time. The delay in bringing forward the Bill is owing to some of the agreements with the telegraph companies being unsettled. Most of agreements required have been arranged, and the terms of the transfer agreed to; but, in the case of Reuter's Telegram Company and the submarine cable portion of the Electric and International Telegraph Company's property, the settlement is still incomplete. Those agreements that simply related to the various land systems of telegraphs, it was easy, from known information and experience. to arrive at the amounts required for maintenance and renewals; but in the case of submarine cables, the average life and annual maintenance are most uncertain elements, depending much upon their position; experience in this special branch of telegraphy has not extended over a great period, and the experience obtained has been most varied. In order to determine the price for Reuter's Telesurface first, and was first retarded, will also use a reachits under surface first, and escape earliest whole of the gutta-percha core has been finished four-wire scale, from Lowestoft to Nordency, on

the Prussian coast, and the amount to be deducted for maintenance and renewal, an arbitration was appointed; this has been sitting for some time, and, from all appearance, it would seem that their labours are far from a conclusion. The decision that may be come to in this arbitration will be taken as applicable to the Electric Company's cable, and so soon as the arbitration is complete, we shall probably see the Money Bill intro-

duced.

The arbitration commenced its sittings on the 15th of March, since which period it has held nine sittings; it is further adjourned to the 8th, and a further postponement will take place. The evidence accumulated during this arbitration will be of the greatest scientific value on the present question. However, in spite of this delay, it is certain that the Bill will be introduced during the present session. It is anticipated that it will meet with some opposition, but there is little doubt that it will pass both Houses. The Post Office have already given notice of a bill for extending and consolidating the present Telegraph Acts, and also for a bill for preventing opposition to the Post Office when they have acquired the telegraph.

The extension of submarine cable from Cuba to Jamaica, Martinique, and other West India islands, is being again brought forward. General Smith, the President of the International Ocean Telegraph Company, who possess and work the cables from Havana to Florida, is now in England, to endeawour to make arrangements for the necessary extension.

NOTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-PLICATIONS

NEW EXPLOSIVES WITH PICRATE OF POTASH-COLOURED FIRES-MODE OF PROTEOTING SILVER WARES-A SILVERING SOLUTION.

FONTAINE is not the only Frenchman who M. FONTAINE is not the only and the has proposed to use picrate of potash as a base or principal ingredient in explosive compounds. He seems to have had a fatal monopoly in the use of chlorate of potash, in conjunction with the picrate; but M. Designolle, it appears is an inventor, who proposes to employ the rather less dangerous mixture of nitrate of potash with the picrate. He proposes, indeed, to make four compounds for as many different purposes, -one for small arms, another for mortars, another for cannons of long bore, and a fourth for torpedoes and shells. Give him, he says, the length and diameter of the bore, and the weight of the projectile, and he will prepare a powder which will give to that projectile any initial velocity that may be desired-For the strongest powder to be used for torpedoes shells, and in mines, he uses only two ingredientspicrate of potash with the nitrate. For use in muskets, rides, and other arms, he adds to the above-named ingredients, a proportion of charcoal.

The proportion of pierate of potash is regulated according to the projectile force required. For muskets and small arms, 20 per cent. of the picrate is employed; in a quick burning powder for artillery, fifteen per cent. is used; and for a slow burnarry, inteer per cent. is used; and for a slow burning powder, for the same purpose, only 8 per cent. The powder is prepared much in the same way as ordinary gunpowder. The ingredients are first wetted, and then ground together in a mill to a very fine powder. The mixture is then pressed into a cake, which is granulated and glazed in the usual way. These operations, we should think, can be performed without danger, as the picrate of potash does not ignite under a temperature of 800 Centigrade. The gaseous products resulting from the combustion of picrate of potash are numerous, and, as will be seen in the following equation, which represents the decomposition, half the carbon is left unburnt:

 $C_{12}$  H<sub>2</sub> (3N O<sub>4</sub>) O, K O = 3N + 5 C O<sub>2</sub> + 2H + O + KO, C O<sub>2</sub> + 6 C.

When nitrate or chlorate of potash is employed, this residue of carbon is, of course, burned. above decomposition represents the changes which take place out of the access of air, as in a gun barrel. When burnt in the open air, the combustion of the picrate gives rise to prussic acid and nitric oxide, the latter, of course, instantly oxidising to nitrous acid.

duction of coloured fires.

proportions:-For a golden yellow fire, parts of picrate of ammonia and picrate of iron; for a green fire, forty-eight parts of picrate of ammonia and fifty-two parts of nitrate of baryta; for red fire, fifty-four parts of picrate of ammonia and forty-six parts of nitrate of strontia.

The loss of silver which results from the impreg-

nation of our atmosphere with sulphur compounds, especially where gas is burned, is very great. It has been said that many thousands of pounds worth go down our sewers annually in the form of dirt from plate cleaning, and the loss of one large house on Cornhill from this source has been described to us as serious. Silversmiths may, then, thank one of their confraternity—Herr Strolberger, of Munich—for a happy thought. He seems to have tried various plans to save his silver, if possible. He covered his goods with a clear white varnish, but found that it soon turned yellow in the window, and spoilt the look of his wares. Then he tried water glass (solution of cilicate of potash), but this did not answer. He tried some other solutions, to no purpose; but at last he hit upon the expedient of doing his goods over with a thin coating of collodion, which he finds to answer perfectly. No more loss of silver and no longer incessant labour in keeping it clean. plan he adopts is this:-He first warms the articles to be coated, and then pays them carefully over with a thinnish collodion diluted with alcohol, using a wide soft brush for the purpose. Generally, he says, it is not advisable to do them over more than once. Silver goods, he tells us, protected in this way have been exposed in his window more than a year, and are as bright as ever, while others unprotected have become perfectly black in a few

A non-noisonous silvering solution—non-poisonous, at all events, in comparison with the cyanide solution, which allows no time for the use of antidotes—though not possibly altogether harmless, may be found useful, especially when it can be applied without the use of electricity. The inventor takes one part of nitrate of silver, and dissolves it in twenty parts of water. To this solution he adds half a part of sal-ammoniac, and precipitates the silver as chloride, which he again dissolves by the aid of two parts of hyposulphite of soda. Afterwards he adds to the clear solution two parts of a milk of chalk and water. When used, the mixture is shaken up, a little poured into a saucer, and rubbed over the article to be silvered with a tooth brush or a linen rag. After rubbing a short time, and rinsing with water, the article, it is said, will be found beautifully silvered.

## PARLIAMENTARY NOTES.

IN the House of Commons, on Monday evening, Mr. Stopford asked the Under Secretary of State for Foreign Affairs what sum had been spent for the purpose of keeping in repair British graves in the Crimea since the termination of the war with Russia; who was or had been responsible for the proper application of any money so spent; and if her Majesty's Government had any recent information as to the present state of the cemetery.

Mr. Otway replied that the last information in possession of the Government was contained in a dispatch which had been received from her Majesty's ambassador at St. Petersburgh, who accompanied the Prince and Princess of Wales in their visit the week before last to the graves of those who fell in the Crimes. Some suggestions had been made as to a better preservation of those graves. He regretted to say that he could not satisfactorily answer the first part of the question, because it would be necessary to communicate with various departments with regard to the expenditure and its application. But as the subject had created a deal of interest, not only in that House, many of whose members fell in the campaign in the Crimes, but in many of the homes of the people in this country, he would ask the hon. member to repeat the question in the course of a short time, and he should then perhaps be able to give him some further information on the subject.

At the same sitting, Mr. Baines asked the Post-master-General whether he would accommodate tradesmen and the working classes by reducing M. Designolle also employs picrates for the protection of coloured fires. The following are his under 20s., 2d. from 20s. to 40s., 3d. from 40s. to test of endurance, but sheer waste of ammunition.

60s., or some similar proportion between the amount of remittance and the cost of the order.

The Marquis of Hartington felt sure that it would be a very great convenience to a large portion of the public if the commission now charged could be reduced. The difficulty in the way of such reduction was that, although the money order system might, as a whole, still be remunerative, there could be no doubt that money orders issued at a smaller rate would be issued at a loss; and he thought it doubtful whether the department ought to undertake any such transactions at a positive loss. He would, however, inquire into the subject and see whether any reduction could be made without a considerable sacrifice to the revenue. We do not think that if matters were properly adjusted at the Post Office there would be any loss to the department, whilst, on the other hand, tradesmen and the working classes would be greatly benefited. We do not think the Post Office should be made a source of revenue. Let it be self-supporting, and let the employés receive fair remuneration for their labours, and give the public the benefit of the rest in reduced charges.

# ON THE PROOF OF GUNS.

BY MR. JOSEPH WHITWORTH, C.E., F.R.S., &c.

THE mode of proof I have lately adopted for my guns consists in preventing the shot from moving when the powder is ignited, the gases generated by the explosion escaping only through the touch-hole. About one-sixth of the regular powder charge fired in this way gives the same strain to the gun as a full charge fired in the ordinary manner. To prevent the movement of the shot, a screw is cut on the periphery of the gun at the muzzle, and on it is fitted a screwed cap having a solid end. The gun is loaded with a cartridge of the ordinary length, but containing one-sixth of the regular charge, and supported by tin discs in the centre of the bore: a flat fronted shot, with tight wads to prevent any escape of gas, and a round steel bar reaching from the shot to the end of the bore, are then introduced and the cap with the solid end screwed on. The gun is then ready for firing, after which my measuring instrument is introduced into the bore, and any enlargement to the 10-1000th of an inch in extent may be ascertained. If there be no enlargement, the powder charges may be gradually increased, until a slight enlargement has been produced. The real strength of each gun is thus positively ascertained, and this strength I would have recorded and stamped upon each gun. This would give confidence to the gunners, and would act as a check on those engaged in the manufacture. When the ultimate endurance of any particular kind of gun is thus to be ascertained, the regular powder charges, or any less quantity deemed desirable, be used, the enlargements being recorded after each discharge. A 9-pounder bore gun made of my metal, but reduced 2in. in diameter, has been so tested, and has had 18 full charges of 11/2 lb. fired from it. The expansion in the bore is now 0.1903in., and that of the outside diameter is 0.0485in. The last discharge was witnessed by 0.0485in. The last discharge was witnessed by Captain Osborne and Mr. Fairbairn, on March 30, 1869. As my object is simply to ascertain the power of endurance, I propose to still further reduce the outside diameter, so as to lessen the num-ber of discharges required before rupture is pro-

During these trials some interesting experiments have been made with different metals for the vent. A copper vent was enlarged by one explosion from 1-10th of an inch to 1-4th of an inch. Experiments have also been made on the compression of different metals by the force of the explosion, from which we shall be able to ascer-tain the strength of powder by comparing the results thus obtained with the compression of the same metals by other means. By this method of proving the endurance, the enormous cost at present incurred may be saved, and I would observe that the present method of proving guns for en-durance with a less weight of powder and shot than that which is known to be the most effective, tends to mislead, and is a waste of ammunition. In the "Times," March 16, 1869, an account is given of the "Endurance of the 9-inch Woolwich Gun," according to which 19 tons of powder were consumed in the trial, but, as more than half the rounds fired were with powder charges, only about one-half the most effective charge, and the remain-der with three-quarters the charge, while all the shot fired were only two-thirds the best weight for

# THE HOT AIR FLARE LIME KILN.

BY MR. J. R. SWANN.

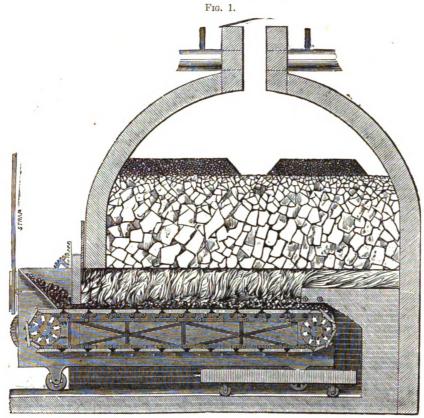

Fig. 2

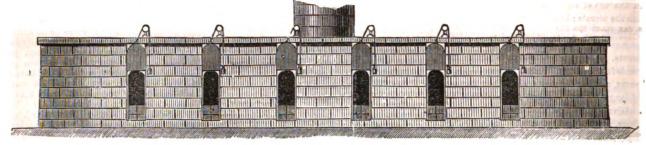

Fig. 3.

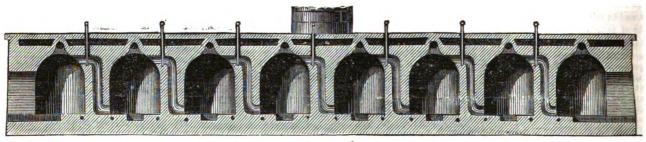

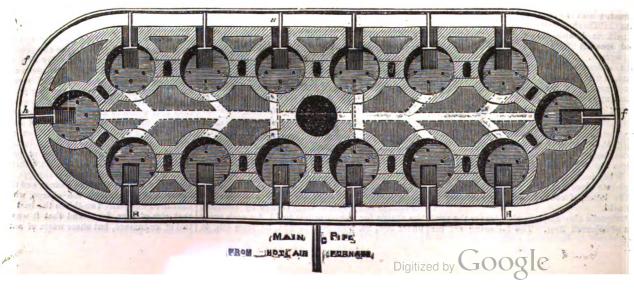

Fig. 4.

WE illustrate herewith a very ingenious lime kiln, invented by Mr. J. R. Swann, of 21, Leith Walk, Edinburgh. It is termed the hot air flare lime kiln, and the principle includes travelling firebars for economy of material and preven-tion of smoke. The kilns are so arranged that the heat passes from the lower to the upper kilns, and by applying heated air, first to drive off the damp, and after to assist combustion, a considerable any ing is effected in fuel and in the time of calcining. It is found, from experiments, that with air heated to 400deg., a 50-yard kiln can be dried in twelve hours without poping, and with half the fuel. Superior lime is prepared by this method, judging by what has been made. By the application of the vapour of petroleum or other liquid fuel vapourized and united with hot air, intensity of heat is generated, giving immense rapidity of production, also effecting a saving in fuel. The firegrate is

SWANN'S HOT AIR FLARE LIME KILNS.

self-supplying, and requires less attention than any other. The fuel is put in a hopper and carried under the door upon an endless chain of short bars (extending the width of the usual firebars), thus forming a travelling grate for the fuel to burn upon. The door is made to slide up and down, and is capable of being set to allow any required thickness of fuel to pass under it; and the chain bars are so arranged as to travel from the door to the back of the kiln, at such a rate as will ensure the fuel being consumed by the time it arrives at back of kiln, and allow the clinkers to down into the ash-pit, or in to a box on

roller in front of the kiln, and another at end of ash-pit, and several smaller ones between. The front roller is arranged to receive motion from machinery, and gives movement to the endless chain bars. The power required is so small that when taken from a steam engine it is quite

wheels, made to run into the ash-pit for that pur-pose. The endless chain bars are carried by one

imperceptible.

The firegrate can at no time, after starting, be covered with bituminous fuel; the supply being gradual from the front end of the kiln, to the back, all the bituminous products are distilled soon after entering the kiln, and pass over coke fire, and thus become completely consumed; consequently, no soot can reach the chalk or issue from the kiln.

The firegrate can never become bare of fuel, neither can air enter the kiln without passing through the fire. The grate can never be clogged up with clinkers to stop free draught, as it discharges the scorize as soon as all the gases are consumed. The labour of firing is reduced to that of putting coal into the hopper, clearing away the clinkers, and occasionally regulating the supply of fuel. The disagreeable work of clinkering, putting coal on the fire, and stirring up, is entirely done away with, excepting at first starting or after long stoppage, and one man can easily attend and fire six kilns. Small coal or screenings are quite as good for these kilns as large coal; this greatly reduces the cost of fuel in price.

In our engraving, fig. 1 shows a section of a flare me kiln. Fig. 2 shows a front elevation of a series of kilns arranged into one general system. Fig. 3 is a longitudinal section of the kilns; and fig. 4 is a plan in section. In this arrangement each kiln has a firegrate A, with firedoors B, and above such doors are other sliding doors C, for filling and discharging kilns; each kiln has a flue D, decending to the floor of the next kiln, and each kiln has another flue E. at the roof leading to the chimney, with dampers to close them when required. The air is heated in like manner to that quired. in which the air is heated for blast furnaces, and is conducted from main pipe G F by branch pipes H, into kilns. Supposing a kiln to be charged with chalk or limestone, the hot blast is turned on and speedily drives the moisture from the stone, which passes to the chimney by the flue E, till it is dried and partially heated. When fires are lighted, the flue E is shut and flue D is opened, as that the heat is driven into the next kiln to sid so that the heat is driven into the next kiln to aid in calcining the limestone in it, the smoke being consumed in its progress.

From experiments already made, superior caustic lime is produced, having a soft tenacious quality, free from core, at a saving of 20 per cent. over the present method. In support of this we append the following certificate from Dr. Macadam, of the Analytical Laboratory, Surgeon's Hall, Edinburgh:—I have made a careful chemical examination of a sample of Sussex chalk, forwarded to me by J. R. Swann, Esq., Edinburgh Saw Mills, and have likewise fully considered the plan of the furnaces which he proposes to employ nace. Several of these ventilators are now at in the burning of the chalk into caustic lime. The work at collieries in different parts of the country,

Sussex chalk possesses the following composition ·--

Carbonate of Lime .		_	_	84.77
Carbonate of Magnesia		•		0.89
Carbonate of Iron .				1.01
Phosphates .				0.13
Silica				1.36
Moisture				11.84

100-00 parts of the Sussex chalk will yield of burned lime 50.17.

From the above analysis, it will be observed that the Sussex chalk is of great purity, and the lime shell of caustic lime obtained therefrom by burning is of first-class quality, and is eminently suited for building purposes and plastering operations.

The mode of burning the chalk into caustic lime proposed by Mr. Swann is ingenious, and is a vast improvement on the ordinary plan of burning. I have satisfied myself by actual experiment, that the employment of heated air in the manner suggested by Mr. Swann for the removal of the moisture from the chalk, and to assist the ordinary coal fire in the after operation of calcining the chalk, and causing the liberation and escape of the carbonic acid, leads to much saving in the actual amount of fuel required to convert the chalk into caustic lime: and I am confident that the plan of calcining proposed by Mr. Swann will turn out first-class caustic lime from the limestone, with a less expenditure of fuel than any of the ordinary methods.

STEVENSON MACADAM, Ph.D.

## INSTITUTION OF MECHANICAL ENGINEERS.

THE general meeting of the members of the above Institution was held on Thursday, April 29, in the Lecture Theatre of the Midland Institute, Birmingham, Sampson Lloyd, Esq., vice-

president, in the chair.

The secretary, Mr. W. P. Marshall, rend the minutes of the previous meeting, and a number of

new members were elected.

The first paper read was a "Description of Guibal's Ventilating Fan Employed at the Homer Hill Colliery, Cradley," by Mr. James S. E. Swindell, of Stourbridge. The fan has eight vanes, and revolves on a horizontal shaft within a cylindrical casing of brickwork, by which it is completely enclosed at the sides and circumference, with the exception of a circular aperture in the centre of one side for the entrance of the air from the mine. and an outlet opening in the circumference for the discharge of the air into the outlet chimney. area of the outlet opening is regulated by an adjustable sliding shutter, according to the extent of ventilation required; and the outlet chimney is built with a gradually Increasing area up to the top, so as to reduce the velocity of the air at the point of discharge, and thereby prevent the loss of power that would occur in discharging it at the velocity of the fan. The fan is driven direct by a horizontal steam engine, working a crank on the end of the fan shaft, without the intervention of The fan at the Homer Hill Colliery any gearing. is  $16\frac{1}{2}$ ft. diameter and  $4\frac{3}{4}$ ft. width, and its usual working speed is twenty-six revolutions per minute. discharging 13,500 cubic feet of air per minute and it can be got up in only about one minute's time to the higher speed of ninety-six revolutions per minute, discharging then 51,700 cubic feet of air per minute. The current of air from the mine passes to the ventilator along an inclined drift leading off from the upcast shaft at a little depth below the top; and the top of the upcast shaft is by a movable cover, which is lifted by the ascending cage on arriving at the top, the weight of the cover being counterbalanced by weights. This is the first mechanical ventilator that has been applied in the working of the South Staffordshire Thick or Ten-Yard coal; and it has now been running about nine months, without a single stoppage for repairs of any description, and is doing excellent work, the total cost of the fan, with engine and connections, being only about one-third of that of an ordinary ventilating furnace for producing the same amount of ventilation. A comparison of actual working between the furnace and the fan at a colliery in the north of England shows that, with a consumption of only two-thirds as much coal, the fan supplies nearly double the amount of air obtained with the ventilating fur-

some of which are as large as 30ft, diameter and 10ft. width, capable of delivering 100,000 cubic feet of air per minute; and they are so free from liability to get out of order that no accidents of any consequence to the ventilation have occurred with any of them.

The next paper was a "Description of the Steam Road Roller Used in Paris," by Mr. E. Gellerat, of Paris, communicated through Mr. George Heaton. This roller consists of a locomotive engine carried entirely upon two large cast-iron rollers of equal size, which are both driven by the engine, the course of the machine being controlled by a special arrangement for changing the direction of the roller axles. The result is that the whole of the weight of the machine is made available both for the rolling of the road and for propelling the machine. The engine is capable of being readily started in either direction without any slipping, and can easily round very sharp curves. machine is the only one which allows all the weight to be made available for adhesion in driving-an indispensable requisite for a really complete rolling machine-none of the weight being dragged; and machines having only one axle driving are liable to slip at starting, causing damage to the road surface to be rolled, and wasting power. Also, the direction of the motion, whether forwards or backwards, being entirely indifferent, is another essential point for rolling roads. By a special mechanical arrangement, the communication of the driving power is maintained direct to both the rollers, however much they may be inclined to each other when traversing a curve; this driving apparatus is made very strong and durable, and it has been found completely successful in work.

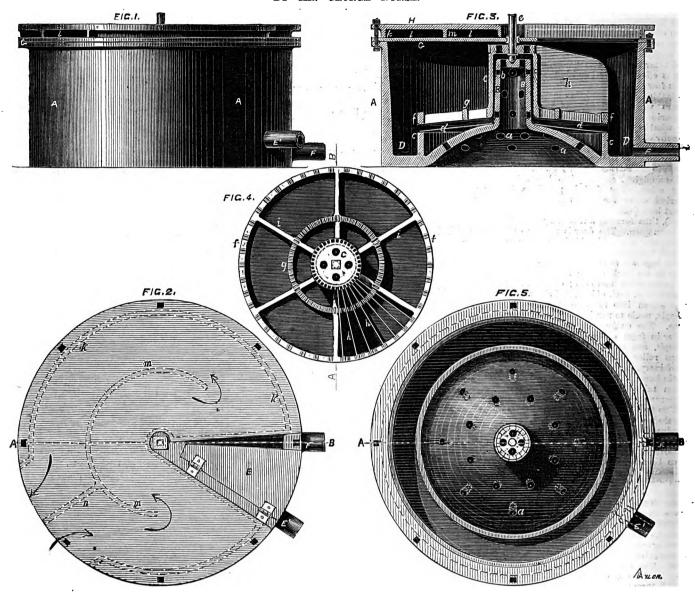

The weight of the machine is equally divided on the two rollers, and the adhesion for driving is so great that these machines have worked up hills with a gradient of 1 in 12½. They are guided with the greatest facility and certainty on the most difficult and winding roads, by the axles of the rollers being made to converge to the centre of the circle which is being traversed. These machines have now been in regular use in Paris for four years, and the results of their working have so thoroughly established their durability and economy that they are used for the whole of the roads in that city and the suburbs. The machine has a longitudinal wrought-iron frame, like a locomotive engine, with cross bearers to carry the boiler, and a water tank at the back of the foot-The two large carrying rollers are 3ft. 10in. in diameter, and 4ft. 7in. in length. They are cast-iron cylinders of 11 in. thickness, with intermediate strengthening ribs and internal flanges at the ends, to which wrought-iron plate covers are fixed. These close the two ends of the rollers, and have cast-iron bosses in their centres for bearings on the axles. The axles are stationary, and the rollers revolve round them with bearings extending the whole length of the roller, and consisting simply of a cast-iron cylinder, with a continuous bearing on the axle, and furnished with a spiral groove for lubrication.

The rollers in the first of these machines were made with separate wrought-iron wheel centres; upon which was riveted a cylinder of boiler plates but this make was abandoned in consequence of the frequent failure of rivets, which were sheared off the stretching of the cylindrical plate from rolling out. The present make of cast-iron rollers, heavier than the original wrought-iron ones, but less expensive in make has proved very satisfactory, and they have done a large amount of work without any expense for repairs, some of them having run as much as 3,000 miles without The first castany sign of cracking or splitting. iron rollers were made quite cylindrical; but it was found that the surface became worn down more at the end next the chain wheel than at the other end; and, to meet this irregular wear, the rollers have since been cast slightly conical, with the larger end towards the chain wheel, so that, when half worn down, they may become truly parallel. One end of each roller has a manhole in it, giving access to the interior for oiling the bearings. There are two sizes of these machines used in Paris—one weighing 15 tons and the other 30 tons in average working order. The smaller one has rollers 3ft. 11in. diameter and 4ft. 7in. in length; the rollers in the larger one being 4ft. 9in. diameter and 6ft. length. machines were adopted for rolling the roads in Paris, in consequence of the satisfactory results of a series of experiments made with them, under the direction of M. Michal, director of the municipal service, by M. Homberg, engineer-in-chief of the public roads of Paris. The machines

# APPARATUS FOR FINISHING TINNED PLATES.

BY MR. GEORGE NURSE.

are hired at a fixed charge, which is regulated by the weight of the machine and the distance run in work; the rate being per ton per mile of the machine, 7d. by day and 8d. by night. This rate includes all expenses of wages, coals, and materials for working and repairs, excepting the supply of water, which is furnished by the municipal authorities. The work of each machine is measured by a self-acting counter, indicating the distance travelled, measured at the mean diameter of wear of the rollers; the measurement of distance being taken only during the actual time of rolling, with an allowance added of three miles for travelling to and from the place of work.

The work is, as a general rule, done in the might within the city, the portion of road repaired during a night being completely finished by the morning, ready for traffic. The speed of working is from 1½ to 2½ miles per hour, being limited to the latter amount by the public regulations. The usual practice in repairs is to lay down a layer of broken stone about 2½ in. thick at the sides of the road, and 6 in. thick in the middle; the surface of the road being generally picked up previously. The rolling engine commences work at the opposite

The work is, as a general rule, done in the night within the city, the portion of road repaired during a night being completely finished by the morning, ready for traffic. The speed of working is from 1½ to 2½ miles per hour, being limited to the latter amount by the public regulations. The usual practice in repairs is to lay down a layer of broken stone about 2½ in. thick at the sides of the road, and 6in. thick in the middle; the surface of the road being generally picked up previously. The rolling engine commences work at the opposite sides of the road; alternately travelling backwards and forwards over a length of about 100 yards, and working its way gradually to the middle of the road, when it proceeds to roll another similar length. The layer of broken stones is watered from the street mains, and binding material, consisting of road scrapings, is put on before the rolling. There is not the slightest difficulty experienced in reversing the motion of the rolling engines, and they start in either direction without any slip whatever, and the broken stone is regularly elled down without getting pushed up or driven before the rollers. The engines start with great

facility, even on a considerable incline, and they turn easily in a circle of only thirteen yards radius. In making new roads, the broken stone is usually laid down in a single layer of 10in. to 12in. in thickness, and this thickness of material can be satisfactorily rolled. The total distance travelled per day of ten working hours by one engine is usually from fifteen to twenty miles. In working, two men are employed for the smaller engines—an engineman and a steersman—and, for the larger engines, a fireman in addition, for the purpose of oiling upon the road without stopping the engine. The mean power developed by the larger engines is about 20-horse power. It is often below that amount, and then sometimes rises to 30 or even 35-horse power. The engines keep well in order, and run 1,200 to 1,800 miles before requiring any important repairs. They are made very strong; the axles, chains, pinions, and working gear being made of steel, and the engin s of the quality of best locomotive work. They are consequently expected to keep at work fully ten years. In reference to the relative cost of rolling roads by the steam roller or by horse power, the following facts may be taken as a comparison of the prices per ton per mile by each plan. The result of numerous data shows the cost of horse rolling in Paris (including horse keep, drivers, and oiling), to be 11d. per ton per mile; or about 11\frac{1}{2}d. including cost of repairs. The addition of interest of capital and depreciation would raise the total cost to about 14d. per ton per mile. On the other hand, for the steam rolling, the actual payment is only half that amount, or 7d. per ton per mile, including the contractor's profit; so that there is great economy as regards cost of power in the steam roller. The advantages of the steam roller over those drawn by horses are economy in the cost of the work,

rapidity of execution, and greater perfection in the work done; the durability of the road surface being found to be at least doubled where the steam rolling has been well done, as compared with roads not so rolled.

The meeting then terminated.

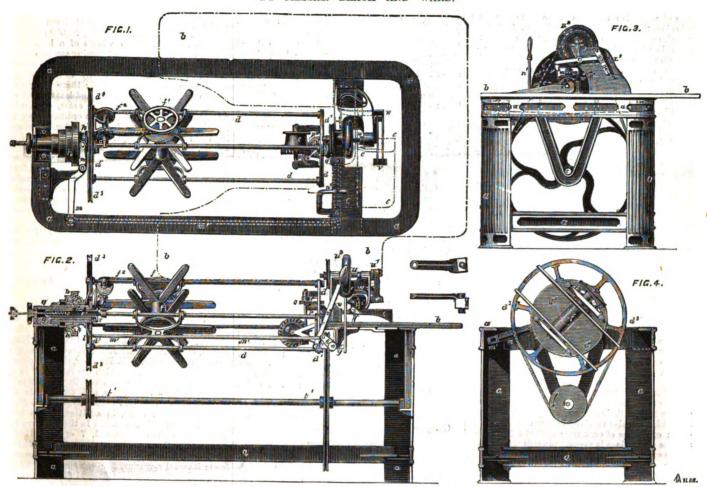

# APPARATUS FOR FINISHING TINNED PLATES.

In the ordinary process of tinning iron plates, the superfluous metal, which adheres to the plates and forms a roughened surface upon them, is removed by the use of what is known in the trade as grease pots. The apparatus we are about to describe is a very great improvement upon this process, which it effectually supersedes. It is the patented invention of Mr. George Nurse, of Pontymister, Monmouth, and consists in constructing the apparatus in the form of a circular pot, with a hollow centre, and with a frame or turntable, which is caused to rotate in the circular hot air chamber. This frame consists of rings formed with studs or projections, to support removable partitions, between which the coated plates are placed, the rings being held by radial arms, carried out from a central support. The cover of the het chamber is provided with a slotted opening through which the coated plates are inserted or withdrawn. The rotation of the frame is produced by a hand-wheel, and as each plate in succession reaches the slot opening it can be taken out and a fresh one inserted. The drippings from the plates fall upon a bonnet, from which they run into an annular space, between the outside of the chamber and a circular flange or fillet, on which the bonnet rests. The drippings may be tapped

#### MACHINERY FOR TWISTING TOBACCO.

BY MESSRS. BLACK AND WARD.

off when necessary by spouts at different heights. Between the cover of the hot chamber and an upper cover flues are formed, through which heat from fires circulates, thereby producing a uniform temperature in the chamber. The brickwork supporting the chamber is situated under the annular space before referred to, so that the metal therein is removed from the direct action of the fires, and, therefore, preserved from oxidation.

Fig. 1 of the accompanying engraving is a side

Fig. 1 of the accompanying engraving is a side elevation of a circular pot, constructed according to Mr. Nurse's invention; and fig. 2 is a plan of the same; fig. 3 is a section of the pot through A B of fig. 2; fig. 4 a plan of the frame; and fig. 5 a similar view of the pot, with the cover removed. A is the circular pot; it is formed with a hollow centre or pillar B, which rises from the bottom. The circular pot A is supported by brickwork or masonry, hollow in the middle, to from a passage for heated air or gases, which is free to enter the pot through the holes ab, provided for that purpose in the base of the pot and in the hollow centre. The inner of the pot has a circular flange or fillet c, for supporting the outer edge of a bonnet d, the inner edge of which fits over the hollow centre, and carries a spindle e, to over the hollow centre, and carries a spindle e, to which is connected a frame, composed of rings f g, formed with rack studs or projections, between which partitions h h are placed, as shown in figs. The rings are connected by radial arms 3 and 4. i to the central support or boss c of the frame. The spindle on which the central frame is fitted has a hand-wheel attached to it, to enable it to be turned in the required direction, when the plates are required to be inserted or with-

The upper part of the circular pot is provided with a cover G which is firmly bolted to the flange or rim. The cover has a slotted opening in it through which the plates are passed; the opening is kept closed while the apparatus is at work by a lid E, as seen in fig. 2. The space D between the inside of the pot and the flange or fillet c forms a channel to receive the liquid metal from the bonthis channel the metal is drawn off by the overflow pipes E 1 and F 1. These are placed at different levels, so that a quantity of fluid metal can be retained in the channel if desired, for the purpose

of keeping up the required degree of heat in the circular pot. Above the cover G is placed another cover H provided with a rim or fillet k of such a depth that a flue or passage l is formed between the two covers. The cover H is provided with a space or aperture corresponding in size to the hinged lid E, so that the opening and closing movements of the lid are not interfered with. under surface of the upper cover H is made with a semicircular rib m, and a radial rib n, as seen in fig. 2, so that the heated air or products of combustion passing through the flue l are caused to take a circuitous route before leaving it.

MACHINERY FOR TWISTING TOBACCO.

N twisting tobacco it is required to enclose A continuous core of tobacco which is slightly twisted in tobacco leaves which are wrapped around the core with a much more rapid twist. article has until lately been produced by hand labour. Improvement, however, which has spread abroad in every other direction, has at length crept in here, and twisted tobacco is now produced by machinery by our leading manufacturers. The annexed engraving represents the tobacco spinning machinery in use at the works of Messrs. Mason and Co., of the Spital Factory, Chesterfield. It is the patented invention of Mr. W. S. Black, of Chesterfield, and Mr. T. Ward, of King's Lynn, who is the sole manufacturer. Fig. 1 shows a plan view; fig. 2 a side view partly in section; fig. 3 an end view; and fig. 4 a transverse section of the machine.  $\alpha$  is the framing; b is a table upon which the tobacco leaves which are to form the core and the outer covering of the twist are laid in heaps. The form of the table b is indicated by dotted lines in the plan view, fig. 1, the table not being shown in full, in order that the form of the framing may be seen clearly; c is a smaller raised table at the points where the core and covering are fed into the machine. The core, as it passes into the machine, lies in the grooves  $c^1$  of the table c; the entrance end of this groove is enlarged, as shown at fig. 2, so that the core, as it is roughly

by means of another workman standing at the side of the machine, these leaves are, by the workman, passed endwise up the incline, and as their forward ends pass under the core which is being revolved, the leaves will be wound up around it. The covering leaves are placed upon the incline  $c^2$  with their ends lapping one over the other so as to form a continuous band, the workman constantly placing fresh covering leaves behind and somewhat overlapping those which are being wound up around the core. d is the frame carrying the capstan e and reel f, upon which the twist is wound up; the frame is composed of two discs  $d^1$  connected together by four rods, as is seen in figs. 1 and 2. The disc at the back end of the machine has a hollow axis  $d^2$  projecting back from it which is capable of revolving freely around the fixed hollow spindle g, which, at its rear end, is carried by the framing of the has rear end, is carried by the framing of the machine. Upon the exterior of the hollow axis  $d^2$  is a driving wheel h formed in steps, upon any one of which a driving belt may be passed; this wheel is capable of revolving freely around the hollow axis, but can be made fast by a coned friction wheel k being forced endwise along the shaft tion wheel k being forced endwise along the shaft by springs l, and so caused to engage with corre-sponding coned surfaces on the interior of the driving wheel. When it is desired to stop the machine, the friction wheel k is moved away from the driving wheel h by means of the clutch lever m (see fig. 1); the end of this lever lies be-tween flanges which pass around the friction wheel, and when the clutch lever is turned to dispurges the friction wheel from the driving disengage the friction wheel from the driving wheel, the two ends of a small projection or enlargement on the under side of the lever near its end are, by the turning of the lever caused to bear against the two flanges, and they put such an amount of friction upon the flanges as at once to stop the axis  $d^2$  and frame d from rotating. The clutch lever is by a rod m 1 connected to a

short arm  $n^2$  on an axis n near the front end of the machine; on this axis is a lever handle  $n^{-1}$  by which the axis can be turned, so that if the workmen fail made up in the hands of the workman, may enter freely into the machine.

The leaves which are to form the covering are fed forward up the inclined side c 2 of the table c; stop the machine by shifting the lever n 1, this

Digitized by Google

lever being in close proximity to both of the workmen. The capstan or drum e is carried by bearings from the disc  $d^{-1}$  which is at the front end of the machine, and it is caused to revolve by a worm wheel upon its axis engaging with a worm, on the axis of which is a toothed wheel o gearing with a wheel on the axis of the bevel wheel p. This bevel wheel, as the frame d is revolved, rolls around the fixed bevel wheel q, and is thus caused to turn on its own axis, and so transmits a revolving motion to the capstan. A tubular passage is formed through the centre of this fixed wheel through which the twist is led as it passes from the groove c 1 of the table c. The axis of the reel upon the twist is wound is supported in frames fixed to the rods of the frame d. On the axis of the reel is a grooved pulley  $f^1$  around which passes a cord  $f^2$ , which is also led over guiding pulleys and around s pulley which can turn freely around a tube r which enters into the end of the hollow axis g. The back end of the tube  $r^{-1}$  is closed, and it is pressed backwards by means of the spiral spring s within it. The strength of this spring may be varied by causing the disc t against which the forward end of the spring bears to move towards or from the rear end of the tube  $r^1$ , and so more or less compress the spring; this is done by turning round the screw stem which carries the disc t.

At the forward end of the tube  $r^1$  is a collar which is by the spring s drawn against the side of the pulley  $r^{-1}$ , and thus the pulley is held against the end of the fixed hollow bearing g, and by this means the rotation of the pulley r is retarded, and so the force with which the reel f tends to wind up the twist can be adjusted. At the back end of the frame d is a grooved wheel d 3 which by a cord drives a pulley on the axis  $t^1$ , and this axis by another grooved wheel gives motion by a cord to a pulley on the axis u, upon which is a grank u which gives motion to the malletor beater v which is to strike against the core of tobacco leaves, and consolidate it just at the point where the covering leaves are applied to it. This mallet is carried by arms which at their rear end are jointed to a link. and which are also received between two pieces of cork; one piece of cork rests against a fixed stop, and the other piece is pressed towards the stop by means of the bent spring w.

The crank which gives motion to the hammer is of such a length that when the mallet is by the crank caused to strike a blow upon the twisted core of tebacco the crank will not have passed over the centre of its stroke, and consequently the spring w has to yield to allow the crank to turn, and thus after giving the blow to the twist of tobacco it gives to it a powerful squeeze. The mallet strikes down upon the twist as it lies in the groove c<sup>1</sup>, and thus the twist of tobacco is unable to escape from the squeeze given to it by the mallet, and this squeezing is given to the twist just at the point where the covering leaves are being lapped around it. The covering leaves will thus be caused to bind tightly around the core. In order that the crank u which works the mallet may be carried round at the time of giving the squeeze to the tobacco twist, a small fly us is placed upon its axis, and in order that the action of the mallet may be at once arrested if the machine is stopped a small wooden brake block w is at this time caused to be forced against the periphery of the fly wheel. The block x is for this purpose carried at one end on a pin  $x^1$ , and at its other end it is connected by a rod to a small arm y on the axis of the disengaging lever; z is a roller which is carried by an arm on the pin z, and this pin is turned by a spring z<sup>2</sup> in such manner as to press the roller against the twist of tobacco and so keep it in the groove c 1,

This machine is used for spinning tobacco into the forms known as "Irish Roll," "Limerick Twist," &c., which has hitherto been spun by hand alone. The machine at Messrs Mason's factory alone. will spin all that can be supplied to it; the quantity produced, therefore, depends entirely upon the dexterity of the feeder. At Spital Factory some of the girls can spin from 500lb. to 800lb. per day, whilst the average quantity spun by hand is, we believe, about 60lb. or 70lb. per man per day. The cost of producing the roll by machine is not more than one-sixth that of hand labour; at the same time, a firmer roll is made. Each machine requires four or five girls to supply the material, and their combined wages amount to less than is usually paid for one man's work.

THE subway from the Tower to Southwark is now advancing at the rate of 9ft. per day, and the con-tractor expects to reach the shaft on the Southwark side in less than five months.

### UNIVERSITY OF GLASGOW.

THE following is the prize list of the class of civil engineering and mechanics of the University of Glasgow, session 1868-9:—Walker prizes. For an oral examination—First, Robert M'Haffle Melliss, jun., C.E., Glasgow; second, Alexander Malcolm, C.E., Balfron. For a written examination—First, Alexander Malcolm, C.E.; second, Robert M'Haffle Melliss, jun., C.E. Class prizes:—For oral examinations—Division A, Alexander Malcolm, C.E.; division B, Richard Niven, Glasgow; division C, James Young, Balloch. For written exercises—Division A. R. M'Haffe Melliss written exercises—Division A, R. M'Haffe Melliss, C.E.; division B, W. Overland Dungar, Gaywood, King's Lynn; division C, Robert W. Maxwell Müller, Glenyards, Denny. (Signed.) W. J. Macquorn Rankine, C.E., LL.D., Professor.

The following have received tickets of proficiency.

in engineering science:—Anthony S. Bower, C.E., St. Neots, Hunts; Waltor Deed, C.E., Colchester; James J. Galloway, C.E., Paisley; James Gillespie, jun., C.E., Garnkirk; Alexander Malcolm, C.E., Balfron; Robert M'Haffie Melliss, jun., C.E., Glasson, M. M. M. G. K. G. G. K. G. gow; George D. Neill, C.E., Greenock; John

Russoll, C.E., Glasgow.

The following are the names of the candidates who have passed part of the course of study and examination in engineering science:—Mathema tics, natural philosophy, geology, civil engineering and mechanics, drawing—James Simpson, Glasgow; mathematics, natural philosophy, chemistry, geology—Archibald B. Allen, Crosshill; Richard Niven, Glasgow; mathematics, natural philosophy, chemistry—Henry Dyer, Glasgow; Robert Napier Glasgow; mathematics, natural philosophy, geo-logy—Robert Stephenson, Inkerman, Paisley; mathematics, natural philosophy—John Wood;
W. Overland Dungar, King's Lynn; geology,
civil engineering and mechanics—Thomas Alexander, Glasgow; geology, A. Cook; William Grant,
Rothsay; R. W. M. Müller, Denny; W. T. Olive.
For the Board of Examiners in

Engineering Science W. J. MACQUORN RANKINE. (Signed) W. J. MACQ Glasgow University, April 28.

EXPERIMENTS WITH PERCUSSION CAPS

OBJECTIONS have of late been raised by the Various great carrying companies to the conveyance of percussion caps, and penalties have occasionally been enforced against senders of these articles. This has led to the interference of the Birmingham Chamber of Commerce in the matter, with the view of testing the explosive or nonexplosive nature of caps when struck in bulk. Accordingly, yesterday week a series of experiments were carried out, at the Ammunition Works of Messrs. E. and A. Ludlow, of Belmont-row. Birmingham. The Government, the leading railway companies, and various underwriting associations, &c., were represented on the occasion. In the first experiment, a tin box containing 250 caps was placed in an ordinary fire, where it remained until all the charges in the caps were burnt out. All the caps gradually burnt, without the lids of the boxes even being blown off, although the lids were well nigh melted. The second experiment consisted in placing half a hundredweight of caps in a red hot muffle; the result was a kind of fizzing at intervals, but there was no explosion. In the third experiment, 50,000 caps were put into a packing case in the ordinary way for transit; these were placed in a furnace; the wood burnt gradually away, but not the slightest explosion occurred; the caps remained stacked in pyramidal form exactly as they had been fixed. A fourth experiment was that of placing within an iron pot, 10in. in diameter, and 10in. deep, a lump of red hot iron, weighing 2lb.; on this 20,000 loose caps were poured, and the pot was filled up with cotton wool; gradually the caps exploded, and the cotton wool became charred, but no flame whatever arose. A lucifer match was put to the wool, which ignited instantly. In the fifth and sixth experiments, brown paper parcels containing 5,000 caps were struck by a mass of iron weighing one hundredweight, and falling from a height of 12ft.; in one of these the box was surrounded by cotton wool, but no explosion occurred. Gunpowder was then substituted for the cotton wool, and, as might have been expected, an explosion occurred; but the mere dropping of the weight on gunpowder alone did not cause an explosion. In the seventh test a parcel containing 5,000 caps

were crushed, but again there was no explosion. Another experiment was that of placing 410 cart-ridges for the Remington rifle in a box; gunpowder was placed within the box, and a fuze applied to one of the cartridges; it alone exploded, the others in the box remained perfect. The party then adjourned to the London and North-Western Railway, where a bag, containing 20,000 caps, was placed on a rail. Two wheels of a locomotive passed over the bag without causing any explosion; at the passage of the third wheel there was a small explosion, but that occurred only to the few caps which were absolutely crushed; there was no explosion in bulk. In the ninth and last special experiment, two wooden packing cases, containing 50,000 caps each, put up in the ordinary way for transit, were submitted for concussion by attaching them to the buffer (not a spring buffer) of an engine. In this test there were employed an engine and three trucks with two brake vans and three trucks; the engine and tender weighed forty When the boxes were struck the engine was travelling at the rate of twelve miles an hour; the boxes were, of course, crushed, and the pieces flew all about, but it was in isolated instances only that the caps exploded. The results of these experiments ought to satisfy the most sceptical that percussion caps are non-explosive in bulk, and are, therefore, practically safe in transit.

### MANCHESTER STEAM USERS' ASSOCIA-TION.

THE last ordinary monthly meeting of the executive committee of this Association was held at the offices, 41, Corporation-street, Manchester, on Tuesday, April 27, 1869, Mr. Hugh Mason, of Ashton-under-Lyne, Vice-President, in the chair, when Mr. L. E. Fletcher, chief engineer, presented his report, of which the following is an abstract:—During the past month 221 visits of inspection have been made, and 489 boilers examined, 279 externally, 7 internally, 6 in the flues, and 197 entirely, while, in addition, 1 has been tested by hydraulic pressure. In these boilers 143 defects have been discovered, 7 of them being dangerous. Furnaces out of shape, 10; fractures, 30 (2 dangerous); blistered plates, 11 (1 dangerous); internal corrosion, 22; external ditto, 22 (3 dangerous); internal grooving, 21 (1 dangerous); external ditto, 4; water gauges out of order, 7; blow-out apparatus ditto, 6; fusible plugs ditto, 2; pressure gauges ditto, 4; boilers without pressure gauges, 1; without feed back pressure

During the stoppage of the mills at Easter advantage was taken of the opportunity for making as many internal and flue examinations as possible of the boilers enrolled, the engineering staff engaged in the office turning out to assist the inspectors in getting inside the boilers and up the flues. In this way a large number of entire examinations were made. The defects met with were not generally of a novel character, so that only one of them merits remark on the present occa-This was a case of fracture, which occurred to a blow-out elbow pipe, from its being tightly bound in the brickwork setting, when the movement of the boiler, consequent either on its settlement or the expansion of the parts, broke it in This occurred when the boiler was in work, and, fortunately, was shortly discovered by the difficulty experienced in keeping up the water level. The objection to binding blow-out albow pipes in the brickwork has been frequently alluded to on previous occasions. The cross wall should be recessed so that the elbow pipe may be quite free, and thus unaffected by the movement of the boiler, be less exposed to corrosion, and at the same time open to view. This arrangement should be attended to in laying down all new boilers, while there is very little difficulty in introducing it in those already set.

Mr. Fletcher reports three explosions, by which five persons were killed and six others injured. The scene of the catastrophe has been visited in two cases by officers of this Association. In the other case, full particulars have not yet been received. Not one of the explosions occurred to boilers under the inspection of this Association. The following is a statement of explosions, from March 27, 1869, to April 23, 1869, inclusive:— April 1, portable agricultural boiler, locomotive type (internally fired), 1 killed, 4 injured; April 19, portable vertical boiler (internally fired), 4 killed, 2 injured-total, 5 killed, 6 injured.

was placed in a box with a quantity of cotton wool.

An explosion occurred at two o'clock on the This was struck by a block of iron weighing afternoon of Thursday, April 1, to the boiler of a 15cwt., falling from a height of 4ft; the caps portable agricultural steam engine, engaged in

# PORTABLE PRINTING PRESS. BY MR. H. HEYER.

thrashing out a rick of barley at a farm yard, and resulted in the death of one person, as well as in injury to four others. The boiler, which was of the multitubular locomotive type, measured 8ft. 6in. in length and 2ft. 4in. in diameter in the Sft. 6in. in length and 2ft. 4in. in diameter in the barrel, or cylindrical portion of the shell, while the thickness of the plates was 5-17ths of an inch, and the load on the safety valve 50lb. The boiler gave way in the outer shell, which was completely destroyed, being rent from the inner casing of the firebox, torn up into a number of small pieces, and scattered in every direction, one to a distance of 90 yards, another to 100 yards, while the smokebox door was thrown to a distance of 150 yards. On the occurrence of the explosion, the son of the proprietor, who was close to the engine at the time, was killed on the spot, while another man standing by him is reported to have been blown up into the air as high as one of the adjoining stacks, while three others were scalded. The simple cause of the explosion was the mal-

The simple cause of the explosion was the mal-construction of the boiler. The manhole was not strengthened, as it should have been, with a substrengthened, as it should have been, with a substantial cast-iron mouthpiece, through the neglect of which so many explosions have from time to time occurred. From this unguarded manhole, which was placed at the crown of the outer easing of the firebox, the primary rent sprung, which, developing in various directions, ripped the shell into fragments. The cover of this manhole was of the dangerous internal class, being carried by a couple of bridges, from each of which two bolts were suspended. An attempt had been made to strengthen the manhole by an external wroughtion ring, half an inch in thickness and one inch in width, but this was attached to the shell by iron ring, half an inch in thickness and one inch in width, but this was attached to the shell by four five-eighths rivots only, while the heads inside the boiler were nearly gone. In consequence of leakage from this joint, the plate, originally 5-16ths of an inch in thickness, was so eaten away that only 1-16th of an inch remained. Had this manhole been strengthened by a suitable cast-iron mouthpiece, the leakage at the cover would not have been eaten away by corrosion, while at the same been eaten away by corrosion, while at the same time the parts would have been strengthened and the explosion prevented.

# THE HOOSAC TUNNEL.

THE Governor of the State of Massachusetts has sent the report of the Commissioners on the and Greenfield Railway and Hoosac Tunnel to the House of Representatives. It is stated in the report that up to February 1 last, the east end heading had been pushed 5,282ft., the east end enlargement 2,500ft., the west shaft heading 4,056ft. and the brick arch finished to a length of The total length to which the headings had been carried at that time was 9,338ft., leaving to be completed 15,693ft. The depth of the ce ntral shaft when finished will be 1,030ft. This shaft has been sunk 583ft., leaving 447ft. to be completed. According to the report of the State

to be completed 15,693ft. The depth of the central shaft when finished will be 1,030ft. This shaft has been sunk 583ft, leaving 447ft. to be completed. According to the report of the State Auditor, the cost of these works, so far, amounts to nearly ten millions of dollars.

HOW ERONZE STATUES ARE CAST.

A MONG the various branches of fine art metal work, the casting of bronze statuary, a chefdourne of Messrs. Elkington's world-famed establishment possess perhaps as many points of interest as any. A leading process of bronze casting is known, says the "Engineer," as the cire perdue, or wax process. A structure of iron bars forming the skeleton of the statue sustains the core. This rough angular outline stands on a kind of platform, having a fire-hole beneath for the purpose of melting the wax when the statue is completed. A mixture of clay, pounded brick, and other material capable of being casily worked when moist, and very solid when dry, is then used for building up the skeleton, so as to present the general contour of the figure, but less than the proposed statue by just the thickness of the metal to be employed. Over all this is placed an equal layer of wax, on which all the details are expressed by the sculptor. "When," says Mr. Altkin, our informant, "the work is satisfactory from every point of view, ascending rods of wax representing channels by which air is to find exit on the metal entering the moulds are placed wherever required. Viewed in this state, the model of the body, which is reached, are external to the model of the body, which is reached, are external to the model of the body, which is not find exit on the metal entering meshwork. The whole model and rods are then painted, over with fine loam in a liquid state, the process being repeated until the crust is strong enough to sustain a thick

loam plaster. It is then bound with iron hoops, and a fire is lighted beneath the platform. The outer coating of wax, exactly representing the metal to be east, is melted out, and the mould is intensely heated until dry enough to receive the molten metal from a reverberatory furnace adjacent to the mould. Jets are made for the introduction of the metal, and the apertures left by the melting of the wax rods afford a ready mode of exit for the air. The plug of the furnace is withdrawn, the flowing metal fills the mould, and the statue is completed. This process is somewhat hazardous, seeing that any defect in the casting would completely destroy the long labour of the artis.

# PORTABLE PRINTING PRESS.

A VERY ingenious and useful article has just been brought under our notice by Mr. H. Heyer, of 101, Leather-lane, Holborn. It is a portable printing press, and is shown in the annexed engraving. It consists of a frame, having a carriage, in which the type is placed. When so placed, with the paper for printing, the tympan is folded down, the carriage pushed in, and the pressure brought upon it by means of the handle, the lower part of which is cam-shaped. A printing "office" accompanies the press; it comprises type, ink, slab, roller, &c., ready for use. These presses are made of various dimensions, and will print from a trade card to quarto size. Common type and ordinary printing ink are used, and the VERY ingenious and useful article has just presses are made of various dimensions, and whin print from a trade card to quarto size. Common type and ordinary printing ink are used, and the apparatus is exceedingly handy and simple. It will be found useful by all who have cards or circulars to print—especially if they require them in a hurry.

### LONDON ASSOCIATION OF FOREMEN ENGINEERS.

usually furnished with four or five. These were supposed to be watertight. Too frequently it was found, in the fell moment of peril, that they were nothing of the kind, and that after a collision it might be said of the vessel that she contained "water, water everywhere," whilst the pumps were incapable of discharging it. Bulkheads were, in ninety-nine cases out of the hundred, illusory and deceptive protectors of iron ships. Vessels of this kind, as now constructed, were calculated well enough for ordinary service under favourable circumstances, but were totally unfitted to contend against the extraordinary accidents which often befel them at sea. It was quite true that the past twelve years had witnessed great improvements in the construction of iron vessels, both as regarded the quality of the material used and in its mode of application. The author of the paper introduced at this point some startling facts which had come under his own notice when engaged as manager for a large shipbuilding company, and which demonstrated very forcibly the haphazard modes of construction commonly practised not many years since. Mr. Rae also took some credit to himself for remedying the evils to which he referred, and especially considered himself entitled to commendation for having been the first to introduce the plate-planing machine into the shipbuilding yard. This apparatus was now almost universally employed instead of, or as supplementary to, the shearing machine, and Lloyd's rules distinctly specify that all "butts" shall be planed. The economy and excellence of iron ship building had been enhanced in a remarkable degree by the use of the planing machine.

The author next addressed himself to the question of internal defects in the construction of iron ships, and pointed out more particularly the weakness which was formerly observable in regard to the head and stern. In 1858 he decided to commence an improved system of connecting the stem and stern to a considerable height, and the solidity of the vessel was thus incre

the Government.

Mr. Rae then proceeded to say that all iron vessels ought to be built with an internal as well as an external iron skin, the latter, of course, being of the greater thickness. Both should be made perfectly watertight. Between the inner and the outer skins a series of bulkheads (say 9ft. apart), and extending from gunwale to gunwale, should be affixed. The spaces between the bulkheads should be filled in with asphalte, so as to prevent water passing from one space to another.

with asphalte, so as to prevent water passing from one space to another.

Such an arrangement would add but little to the original cost of the ship, whilst it would increase her strength fully 50 per cent. A ship was, indeed, "a thing of beauty," as well as a valuable minister to the wants of mankind, and it was the duty of an enlightened country like ours to frame stringent laws for governing its constitution, and thus to promote the safety of those who entrusted their lives to the ocean.

the ocean.

Mr. E. J. Reed, Chief Constructor of the Navy, commenced the discussion which followed the paper, and in doing so said that he agreed with its author as to the generally faulty construction of iron ships as built some few years since. Even now he thought that legislation might be beneficially employed in regard to the construction of iron ships for commercial purposes. He considered that the Admiralty had not acted unfairly towards the reader of the paper. That gentleman had, no doubt, discovered the weak points to which he had referred in

regard to the stems and sterns of the older iron

regard to the stems and sterns of the older iron ships, but so had many others, and it was hardly to be expected that so self evident an improvement could come under the prohibitory provisions of letters patent. For himself (Mr. Reed) he had a dislike of patents generally.

As to the double skinned vessels with "asphalte" filling between the bulkheads, he had little faith in it. The ship in such case would be permanently loaded very much to her detriment, whilst the contingent advantage was problematical. He wished also to say that in every instance where bulkheads were used in the Royal Navy, their watertight qualities were tested by hydraulic pressure.

Mr. Wearing combated some of the propositions of Mr. Reed, and considered that the Government was rather apt to appropriate the inventions of those who submitted them for consideration. The patent system was, on the whole, good, but it required some modifications.

modifications.

Mr. Vinnicombe defended the Government from

Mr. Vinnicombe defended the Government from the charges made against it.

Mr. Campbell followed in the same direction, and cited cases where compensation had been awarded for valuable communications.

Messrs. Stabler, Taylor, Clark, Ives, Walker, the chairman, and others, continued the discussion, and, finally, a vote of thanks was unanimously awarded to Mr. Rae, who, in returning thanks, took occasion to reply to some of the objections of Mr. Reed and others who had differed with his (Mr. Rae's) propositions. At a late hour the sitting terminated.

### APPEARANCE OF A COMET.

TELESCOPIC comet is at present visible, and A TELESCOPIO comet is at present visible, and is likely to remain so for an unusual length of time. It was discovered near the beginning of last month by Dr. Winnecke, at Karlsruhe, and has been identified with Pons's comet of 1819 and Winnecke's of 1858—a small comet with a period of only five and a half years. It is expected to come to its perihelion about June 30, and to be again seen afterwards, though chiefly in the southern hemisphere, until September. In the great length of period of its visibility and the short elliptical character of its orbit, it is therefore something approaching the wards, though chiefly in the southern hemisphere, until September. In the great length of period of its visibility and the short elliptical character of its orbit, it is, therefore, something approaching the planetary, though as to its physical structure it is cometic in the extreme, for all that a six-inch object glass would show on Friday night—the finest observing night, too, for months, and with the comet at so large an altitude—was a faint speck of vapour (barely visible under a low power and vanishing under a high one), about three or four minutes in diameter, and slightly concentrated towards a nearly central nucloid point. Its position in the sky on last Friday night, at half-past ten o'clock, says a writer in the "Scotsman," was in right ascension 9 hours and 58 minutes, and in declination 36 degrees and 39 minutes, so that it is high up to the south and a little to the west of the meridian when twilight ceases; and its motion is very slow just at present, with a right ascension decreasing and declination increasing slightly, but about to stop and then change to decreasing. As the comet during the next two months comes every day nearer its perihelion, and becomes illuminated by a stronger and stronger solar sight—the sun each day subtending in its sky a large angle—it will be visible in smaller telescopes wherever a dark night can be commanded; but that will not be in Edinburgh or northward thereof, where for several weeks on either side of June 21 there is no true darkness, but a gloaming instead, which will probably outshine the comet, even at its brightest and best. We cannot, therefore, hold out to the public any promise of a brilliant display to the physical eye, though the mental vision may wonder admiringly at a barely visible and formless patch of thin mist, knowing its proper path of several hundreds of millions of miles in circuit round the sun, and describing every part of that path with such them with theoretic perfection, while on the other it enables all the chief events of its past histo

## A WEEK'S WORK IN BIRMINGHAM.

A WEEK'S WORK IN BIRMINGHAM.

A WEEK'S work in Birmingham in its aggregate results is something wonderful. According to the "Engineer," it comprises the fabrication of 14,000,000 of pens, 6,000 bedsteads, 7,000 guns, 800,000,000 copper or bronze coins, 20,000 pairs of spectacles, 6 tons of papier maché ware, £30,000 of jewellery, 4,000 miles of iron and steel wire, 10 tons of pins, 5 tons of hair pins, hooks and eyes, and eyelets, 180,000 gross of wood screws, 500 tons of nuts, screw bolts, spikes, and rivets, 50 cons of wrought-iron hinges, 350 miles length of wax or vestas, 40 tons of refined metal, 40 tons of lerman silver, 1,000 dozens of fenders, 8,500 fellows, 1,000 roasting jacks, 150 sewing machines, of the Institute, who subscribe £ each is 100 tons of brass and copper wares, besides and silver, who subscribe £ each is 100 tons of brass and copper wares, besides and silver, who subscribe £ each is 100 tons of brass and copper wares, besides and silver, who subscribe £ each is 100 tons of brass and copper wares, besides and silver, who subscribe £ each is 100 tons of brass and copper wares, besides and silver, who subscribe £ each is 100 tons of brass and copper wares, besides and silver, who subscribe £ each is 100 tons of brass and copper wares, besides and silver, who subscribe £ each is 100 tons of brass and copper wares, besides and silver, who subscribe £ each is 100 tons of brass and copper wares, besides and copper wares.

almost endless multitude of miscellaneous articles, of which no statistics can be given, but which, like those enumerated, find employment for hundreds and thousands of busy hands, and are destined to supply the manifold wants of humanity from China to Peru.

# Correspondence.

THE MYSTERIES OF "HERCULES."

TO THE EDITOR OF THE "MECHANICS' MAGAZINE." SIR,—I believe the ship "Hercules" to be as good a specimen of hand-craft as any vessel afloat; why, as Mr. Holland says, should she not be called a "spade?" A plough were more appropriate. In her rapid passage through the water she turns over a beautiful wave furrow, the sea runs up the incline how they chestra era rendered useless and her a beautiful wave furrow, the sea runs up the incline bow, her bow chasers are rendered useless, and her wing guns nearly so. When would I fight such a craft? In a stiff breeze, with a breaking sea. If she attempted to give battle with her wing guns, those huge fillers cut out of the sides of the otherwise good ship, asthings go, would drown the men out of the central battery. It is all very well to hear that she behaves like a duck in calm weather. Has she ever been haves like a duck in calm weather. Has she ever been in a gale of wind across the Atlantic? And what is the use of a ship of war that cannot fight in a stiff breeze. We seek shelter when such occurs in an ocean battle. We hear that she is as good a vessel as any our friends have. One of the advantages claimed is her cheapness; she is the most expensive vessel ever constructed for coast and harbour defence. As regards an ocean cruiser she is nowhere. The nominal power in her is great—double than The nominal power in her is great—double than what has appeared in print. If six times the nominal what has appeared in print. If six times the nominal measures were developed, how long would the coals last? Could she steam forty hours chased by a much swifter ship. She could barely do so with 600 tons of coal, steaming 8,258 tons horse power. It is argued that to increase her length would increase the armour. Well, I think that is quite clear; but to give her seven beams in length would likewise increase the coal stowage. Then it has been stated that the ship would be bigger, and we would require more men to keep her clean. I think the cleanness of the ship is of little account in the din of battle. What with fire engines and what-not, little need be said about such paltry technical arguments in time of peace. Next, she is termed a handy vessel. Very, I should not think, in the middle of in time of peace. Next, she is termed a nanay vessel. Very, I should not think, in the middle of Atlantic.

This brings me to ask, What is war? I take it to be destroying our commerce, seizing all our merchant ships on the broad ocean. Could the "Hercules" prevent this? She may take a day's cruize from our shores, but we must remember coals are not to be had at sea. I sthe mystery unravelled. I think partly; and it is this, that when shipbuilders provide ships for the mercantile marine they give sufficient coal stowage to suit the requirements.—I am, Sir, yours, &c.,

DETECTOR.

[Our Correspondent will find his "mysteries" unravelled at page 326, where we have discussed the above somewhat spasmodic communication.—ED. M. M.]

# VELOCIPEDE INSTITUTE.

VELOCIPEDE INSTITUTE.

SIR,—I beg to forward you a copy of a letter I have addressed to the President of the Board of Trade, thinking that the formation of the Imperial Velocipede Institute may be interesting to many of your readers, from whom I shall be very glad to receive suggestions.

I trust you will lend to such society, having a useful object in view, your valuable assistance.—I am, Sir, yours, &c., Alf. D. DE LAVIGERIE.

6, St. Swithin's-lane, E.C., May 5.

6, St. Swithin's-lane, May, 1869.

SIR,—Some friends and myself, having considered the general usefulness of velocipedes, and especially the use which the French Government is now makthe use which the French Government is now making of them, by supplying with one of them every telegraphic messenger, and most of the country postmen, it is our intention to form, at once, in England, a society having the following objects:—

1st. To give prizes for the best velocipedes or carriages for public roads having any motive power excent horses.

per annum, and, thirdly, ordinary memers sub scribing  $\pounds$  per annum each. No profits in money is to be divided among the

members, but a secretary, manager, solicitor, and teachers, may be employed with salaries. The society to be conducted by a committee of not less than three and not exceeding fifteen members.

It is also intended to publish either books, pamph-

It is also intended to publish either books, pamph-lets, or a newspaper, to advocate the objects of the society, or to make arrangements with a publication already established. And I have now to ask you to be good enough to inform me whether, in the event of such a society being properly framed under the Companies Acts, 1862 and 1867, and not being one formed for profit, you will authorize it, and give it the privileges of the 23rd section of the last-named Act of Parliament.

I have the honour to be, Sir, Your most obedient servant, ALF. D. DE LAVIGERIE.

The Right Honourable John Bright,
President of the Board of Trade.

[It is true that M. Drouze succeeded in inducing the French Government to mount a certain number of rural postmen upon velocipedes, but an accumulation of ice and snow put a stop to the enterprise, which had not sufficient vitality to revive.—
ED. M. M.]

### TO CORRESPONDENTS.

THE MECHANIOS' MAGAZINE is sent post-free to subscribers of £1 ls. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

of £1 ls. 8d, yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANIOS MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANIOS MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED, M. M.

Advertisements are inserted in the MECHANIOS MAGAZINE, at the rate of 6d, per line, or 5d, per line for 13 insertions, or 4d, per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

SAT.—Royal Institution.—Professor Seeley on "Roman
History," at 3 p.m.

# Nabal, Military, and Gunnery Items.

DURING the past week 39 wrecks have been reported, making for the present year 979.

THE annual regimental dinner of the 60th (King's Royal Rifle Corps) will take place on Wednesday, June 2, at the London Tavern.

It having been found that the rammers of Snider breech-loading rifles are apt to injure the barrels in cleaning, the square heads are to be filed round by armourer-sergeants of regiments, without expense to the public.

THE annual regimental dinner of the Royal Regiment of Artillery will take place on Tuesday, June 1, at Willis's Rooms, King-street, St. James, when the Duke of Cambridge, as colonel of the regiment, will

THE Lords of the Admiralty have accepted the tender of the Australian Meat Company, for whom Messrs. John M'Call and Co. are the London agents, for the supply of 200,000lb. of Australian preserved

THE French soldiers, acting in small parties, have been instructed to make a temporary rampart with their knapsacks, over which they throw their brown-coloured blankets. Behind this shelter they can crouch, either using it for the purpose of hiding them entirely from the enemy or for protection.

THE Soldiers' Monument at Rock Island, Illinois, was dedicated on the 9th ult. An imposing military parade took place, participated in by the United States troops, and a large number of citizens from Iowa and the surrounding country were present. The Hon. E. A. Storrs, of Chicago, delivered the oration.

An ironclad sloop of war, built by the Thames Iron Works and Shipbuilding Company for the Turkish Government, was launched from Blackwall on Wednesday week, and was named the "Avrii Illah." The Turkish Ambassador was present, and the launch was successful, the ship being christened by Mdlle. Musurus, daughter of His Excellency. The ship is of 1,400 tons; she carries four 12 long guns, in an apexagonal battery; and the armour plates are 6in. thick, with a 10-inch teak backing.

A FEBJEE Island correspondent of the "Honolulu Gazette" says there are at Libruka, on the Island of Ovalan, about thirty foreigners, all sailors, most of whom have run away from ships and turned Feejeeans. The principal man among them, and the one who has most influence with the chiefs—and, in fact, is a very respectable and steady man—is David Whiffey, who, thirty years ago, left a Nantucket whaler, and, making friends with the chiefs of Libruka, settled there. He has a number of wives and a large family.

The breaking up of the ice in the Volga has occasioned a serious accident near Nijni Novgorod, at the village of Pietchera. The blocks of ice carried down by the current have destroyed three steamers, one of 200-horse power, and the other two of 80 each. The iron shells of these vessels, the engines, and the boilers, were all smashed, and shortly afterwards sank. The loss is estimated at nearly £30,000. Eight boats and a landing erection in wood were also dashed violently against each other and broken up. Fortunately, no personal injury was sustained.

THE Board of Trade have awarded a binocular telescope to Captain J. B. Opisso, of the Italian barque "Franco," of Genoa, for having rescued the master and crew of the British ship "Sunderland," from their sinking vessel on March 14. The "Sunderland," soon after leaving Liverpool for Boston, experienced a heavy north-east gale, during which she sprung a leak, and the master finding all efforts to save her fruitless, abandoned her in lat. 49 30, long. 11 W. He and his crew, eighteen persons in all, were received on board the "Franco," and after being treated with great kindness were landed at Malaga on March 23.

THE "Devastation," one of the new turret ships ordered to be built, and referred to by Mr. Childers in his exposition of the Navy Estimates, will be constructed in No. 7 dock of Portsmouth yard, where half of her midship section has been temporarily set up in wooden batten frames. The side armour will project from the ship's hull proper, from a depth of oft. below the water line to deck level, somewhat on the principle adopted in the American navy for turret vessels. The "Devastation" will be commenced immediately No. 7 dock is vacated by the Royal yacht "Victoria and Albert," now being built there, whose date of completion is fixed for the end of the present month.

# Miscellanen.

ONE of the Nevada gold mines, the Yellow Jacket, was opened on the 18th ult., and it was found that the subterranean fire was still burning; but there were no indications of fire in either of the others.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending May 1, was 3.742. Total number since the opening of the Museum, free daily (May 12, 1858). 1,557,576.

UPWARDS of 100 gold coins, some of them belonging to the reign of Henry VIII., were recently discovered at Dunblane while an old house was being pulled down. The coins are in a good state of preservation. It is said that the value of the metal is about £80.

A PARLIAMENTARY paper has just been published, which shows the number of cotton, woollen, shoddy, worsted, flax, hemp, and other factories subject to the Factories Act in each county of the United Kingdom, and giving many other minutiæ respecting factories. In the whole kingdom there are 6,403 factories, in which 854,243 persons are employed.

YEARLY the quantity of wheat brought into this country from Russia increases. For instance, in February, 1869, wheat to the value of £469,099 was imported, against £368,960 in the corresponding period in 1861. Of course it is well known that our supplies of wheat from Russia are much in excess of other countries, even the United States.

The town of Chartres has voted the sum of £200 for the purchase of pictures at the exhibition, which opened there on May 1, at the same time as the regional agricultural exhibition. It is announced that the Empress, and probably also the Emperor, will pay the town a visit on the occasion of its combined exhibitions of industry, art, and archeology.

THE first public Acts of the present Parliament have just been issued in a new form. The cumbrous folio in which such acts have hitherto appeared has been superseded by a handsome imperial 8vo, in bold type, and with sufficient margin. We understand that this convenient form has been adopted in connexion with a revised edition of the statutes which is being prepared for publication.

A CURIOUS experiment is said to have been recently performed in France to ascertain whether fishes can live in great depths of water. The fish were placed in vessels of water made to sustain 400 atmospheres, under which they lived and preserved their health. It is therefore concluded that fishes may penetrate to very great depths in the ocean with impunity.

The higher ranges of fells and mountains around the lake district of Westmoreland were covered with snow on Monday morning to the depth of 3in. or 4in. The cold was remarkable. During the day heavy falls of rain occurred, accompanied by a sharp breeze from the north-west. On Saturday the thermometer registered 90deg. in the sun; on Sunday the mercury fell to below 50deg.

The number of visitors to the South Kensington Museum during the week ending May 1, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 12,978; Meyrick and other, galleries, 2,483; on Wednesday, Thursday, and Friday (admission 6d.) from 10 a.m. till 6 p.m., 2,362, Meyrick and other galleries, 204; total, 18,027, Average of corresponding week in former years 12,362. Total from opening of Museum, 8,393,905

At the ordinary meeting of the Society of Engineers, held on the 3rd inst., Mr. F. W. Bryant, president, in the chair, a paper was read on "The Systems and Apparatus Employed for Illumination by Coal Gas," by Mr. William Sugg. The following candidates were balloted for and duly elected as members, viz., Messrs. W. Walker and J. T. Lloyd; as associates, Messrs. P. Gray and F. S. Ultzen. The ordinary meetings of the Society were adjourned until Monday, October 4 next.

It has been determined by the Sheffleld, the Great Northern, and the Midland Companies to proceed with their new joint line from Manchester to Liverpool, the three companies having concurred in releting the works which they believe can now be executed upon more favourable terms. On Monday, in consequence, the directors of the Manchester, Sheffield, and Lincolnshire Company issued their allotment letters for £1,000,000 new ordinary stock, at 50 per cent. discount.

THE heads of the French Post Office and of the Telegraphs have concerted together on the terms of a bill to permit the transmission of money orders by telegraph. The sum deposited will have to be described in the message both in writing and figures, and all the rules now in force, as well as the tariffs, will be applicable to these dispatches, which on arrival at their destination will be sent to the Post Office, and notice given to the person to whom they are addressed.

REPORTS are again current in the Californian papers of great discoveries of gold in Alaska, the territory recently acquired from Russia. They are stated to have been made by a Russian engineer, who was prospecting in consequence of having obtained specimens from the Indians. On account of the climate, however, the mines can only be worked five months in the year, and the hard and uninviting character of the country is considered likely to preclude any very general attempts for their development.

WE are informed that the great project for the construction of the Darien Canal, discussed by us in our issue for March 12 last, has fallen through. It appears that the congress of the United States in session at Bogota has rejected the treaty, as has also thecongress at Washington. Here, then, is an opportunity for English engineers, contractors, and capitalists to carry out this important undertaking, in which they can have the co-operation of an influential company which has already been formed in New York, and which has funds at its command.

WE learn that a bill for the inspection of steam boilers has been introduced into the Pennsylvania Legislature. It provides that within thirty days the Governor shall appoint one suitable person, to serve for three years, in each Congressional district, as inspectors. They shall examine all except locomotive and low pressure boilers, and shall keep a "lock up" safety valve on each boiler. The owners shall have their boilers ready for inspection when notified, and shall pay four dollars for inspection and shall attach a low-water indicator, connected with the steam whistle.

THE "Moniteur" announces that on Sunday week the Emperor Napoleon gave a private audience to Lord Richard Grosvenor, as the promoter of a proposed submarine tunnel between Calais and Dover. The "Moniteur" does not pretend to state what passed at this interview, but it believes that his Majesty considers the tunnel scheme to be beset by difficulties; while, on the other hand, he thinks highly of the bridge over the Channel projected by M. Boutet. He even suggested, on seeing the model of the bridge, that the number of piles on which it is to be supported should be doubled.

An interesting meeting, "Concours Regional," was held last week in the department of Moulins Allier. An unusually keen competition took place for the prizes for ploughing, particularly for the best deep ploughing (charrue profonde). In the best agricultural districts of France the ploughing is much deeper than is practised in England. The native manufacturers had evidently made considerable progress since the International Exhibition of 1867; yet they fell far short of their old rivals, the Howards, of Bedford, who again carried off the first prize, and who succeeded in turning the soil well over to a depth of 16in.

THE Council of the Society of Arts offer the Gold Medal of the Society, and the large Silver Medal of the Society, for the best and the second-best block model of a steamer, which shall afford the most convenient shelter and accommodation to passengers on the deck of the vessels cruising the Channel between France and England. The steamer is not to e xceed in tonnage and draught the best vessels now in use between Folkestone and Boulogne, and the model must be on a scale of a quarter of an inch to a foot. The models, marked in cypher, are to be sent in to the Society of Arts' House, John-street, Adelphi, on or before November I next, with a sealed envelope, giving the name and address of the designer.

At the meeting of the Institution of Civil Engineers, on Tuesday, the 4th inst., Mr. Thos. Hawksley, vice-president, in the chair, the following candidates were balloted for, and declared to be duly elected, including nine members, viz.:—Mr. V. G. Bell, Mr. V. Browne, Mr. B. S. Brundell, Mr. J. B. Eads, Mr. C. C. Fishe, Mr. G. Fisher, Mr. F. W. W. Luders, Mr. R. Moreland, and Mr. B. Samuelson, M.P. Eleven gentlemen were elected associates, viz., Mr. J. C. Bunten, Mr. J. Collinson, Mr. E. G. Davenport, Mr. A. C. Jenour, Mr. H. de la Poire Murphy, Mr. J. Noble, Mr. F. B. Passmore, Mr. T. C. Rayner, Mr. A. Terry, Mr. A. A. Wickenden, and Mr. J. S. Winbolt, M.A. The council have recently admitted Messrs. A. S. Busk, J. Doull, and C. P. Gibbons, as students of the Institution.

At the general monthly meeting of the Royal Institution, held last Monday, Sir H. Holland, Bart., President, in the chair, the following vice-presidents were nominated for the ensuing year:—The Duke of Northumberland; Mr. William Spottiswoode, F.R.S., the Treasurer; Mr. J. P. Gassiot; and Mr. G. Busk. Lieut.-Colonel Archibald Campbell Campbell, Sir William Dickason Clay, Bart., Mr. W. W. Ford, Mr. J. B. Marsden, and Mr. Herbert Schloss, were elected members of the Royal Institution. Professor J. Tyndall, LL.D., F.R.S., was relected as Professor of Natural Philosophy. The managers announced that in conformity with the deed of endowment, they had appointed Michael Foster, M.D., F.L.S., Fullerian Professor of Physiology.

The value of the principal (the enumerated) imports into Belgium in January, 1869, shows an increase of 11 per cent. as compared with January, 1868; and the principal exports an increase of 16 per cent. The increase of exports is very marked in the items of glass, paper, eggs, beetroot, sugar, and wheat. There is a large increase in the export of iron rails, sheets, wire, and nails, and in the import of iron ore. The export of machinery amounted to 411,062 kilogs., and the import of 341,193 kilogs., 264,255 kilogs. of this last item being from the United Kingdom; the export of machinery was chiefly to Zollvercin States, France, and Holland. There was an increase in the imports of soda, barley, fish, flax, copper, rice, and oil seeds; and the import of textile manufactures shows an increase.

The velocipedomania is still spreading. Last winter an ice velocipede, running on steel slides and propelled by means of a wheel furnished with sharp points, was brought out at Stuttgart, but it was much objected to by skaters on account of its spoiling the ice. We now hear that a party of Prince Napoleon's aides-de-camp have made a trip from Nice to Villafranca on water velocipedes. These machines consist of two miniature parallel cances which support a sort of chair; the paddle-wheel, placed between the cances, is propelled by the feet only, and is covered like the paddle-wheel of a steamer to protect the driver from the water it throws up. Their speed is said to be very great. It now remains, says the "Pall Mall Gazette," for the Aeronautical Society to adapt the velocipede to travelling through the air.

# Patents for Inbentious.

### ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment: ment:

ment:—
BOILERS AND FURNACES—3213, 3232
BUILDINGS AND BUILDING MATERIALS—3191, 3231
CHEMISTRY AND PHOTOGRAPHY—3202, 3203
CULTIVATION OF THE SOIL, including agricultural implements and machines.—3225
ELECTRICAL APPARATUS—3224
ELECTRICAL APPARATUS—3225
ELECTRICAL APPARATUS—3224
FIBROUS FABRICS, including machinery for treating fibre pulp, paper. &c.—3185, 3186, 3187, 3199, 3219, 3221, 3243, 3244, 3244, 3249, 3259
FOOD AND BRUERAGES including the apparatus for year

FOOD AND BEVERAGES, including the apparatus for pre-paring food for men and animals—3184, 3194, 3204, 3220, 3250

3250
FURNITURE AND APPAREL, including household utensils time-keepers, jewellery, musical instruments, &c. ... 3189, 3193, 3207, 3208, 3209, 3211, 3212, 3215, 3216, 3217, 3246, 3253, 3261
GRNERAL MACHINERY —3183, 3205, 3206, 3210, 3214, 3228, 3229, 3230, 3235, 3239, 3252, 3255
LIGHTING, HEATING, AND VENTILATING—3176, 3180, 3190, 3198

3198
METALS, including apparatus for their manufacture—
3181, 3237, 3240, 3247, 3248, 3254, 3256
MISCRLLANEOUS—3175, 3177, 3178, 3242
BOADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—3179, 3188, 3195, 3201, 3227, 3234, 3257
SHIPS AND BOATS, including their fittings—3200, 3226, 3251, 3258
STRAM ENGINES—3174, 3197, 3233, 3241, 3260

, 3235 | Engines—3174, 3197, 3233, 3241, 3260 | Are—317**3,** 3182, 3192, 3196, 3222, 3223, 3236

3173 C. Churchill, Norwood. Breech-loaders. (A communication). Dated October 16, 1863.

The breech-piece is formed upon a tail-plate, and carries tubes or nipples which communicate directly with the interior of the barrels. The breech-piece extends forward, forming a frame to which the barrels are hinged; projections formed on the under side of the barrels, which, when the breech is closed, lies in a corresponding recess in the frame. A bolt passes through the breech-piece into a-hole in the rear of the barrels when the breech is closed, and thereby locks the barrels firmly, and keeps them from being accidentally raised. To operate the said bolt to release the barrels, the patentee piaces in the rear of the same a sliding bar, which extends down through the trigger guard plate, and is provided with a finger plate, whereby it is manipulated. The bar is forced downward by means of a spring. The upper end of the bar is forked, so that one leg passes up on each side of a flattened portion of the locking bolt. The rear surface of this forked portion is inclined, and a head or pin on the bolt rests upon the inclined surface, so that by moving the bar upward, its inclined portion acts on the head of the bolt, the same being thereby drawn back, and the barrels released.—Patent completed.

3174 L. ASHCROFT, New York, U.S.A. Safety valves, Dated

October 18, 1868

October 13, 1868.

This consists in the construction of the valve and its seat, and their relation to each other, and in the arrangement of the same, and its sustaining dome and inclosing case in such manner that the steam shall be at all times in direct communication with the face or faces of the valve by means of circular openings in the valve seat, into which steam is directly admitted from the boiler through the dome and through inlet openings in the steam chambers of the valve seat.—Patent completed.

3175 A. DENAYROUZE, Paris. Dresses for divers. Dated

r 16, 1869

October 16, 1869.

The improved dress for divers is made of india-rubber or other similar waterproof material, and has sleeves and cuffs. A collar of elastic fabric is sewn or otherwise attached to the neck. The horizontal portion is perforated with holes. The helmet or head-piece for divers consists of two parts—a spherical part, which covers the face and back of the head, and a collar or neck-piece. The spherical part has holes in it, in which eye glasses are placed. The bottom of the spherical part and the top of the collar or neck-piece are fitted with rings, in which are holes corresponding with those on the collar of the dress; these rings are covered with caoutchouc.—Patent completed.

dress; these rings are covered with caoutchouc.—Patent completed.

3176 J. PHILLIPS, Hampstead. Warming and ventilating. Dated October 16, 1863.

The hot water pipes conveying the upward and downward currents between a boiler below and cistern or expansion chamber above, are enclosed within air tubes or passages, which may be placed or constructed within the partition or other walls of a dwelling house or other building. Openings are formed into the air tubes by preference in or near the ceiling of each room with which they communicate, through which openings the vitiated air passes into the air tubes and away to the outlet through the roof, a strong upward current being produced in the air tubes by the expansion of the air therein caused by the heat evolved from the surface of the hot water pipe enclosed within such air tube or passage.—Patent abandoned.

3177 E. T. HUGRES, Chancery-lane. Adhesive substance. (A communication). Dated October 17, 1868.

The skins of rabbits are chopped or cut up into small strips or filaments placed in a water bath and boiled. This solution is then emptied into any suitable vessel perforated at the bottom, so that the juice or liquid portion of the solution may flow through the perforations into a vessel provided for the purpose, and a solution of about four parts of sulphate of zinc to one of alum is added thereto while the liquid portion of the before mentioned solution is still hot. This mixture is well stirred, and

passed through a sieve, after which it is emptied into a passed unrough a sieve, after which it is emptied into a rectangular or other shaped box, in which it is left to solidify or congeal. The congealed mass is then cut in two pieces, and each piece placed in a suitable box, where it is again cut up into thin leaves or cakes of the required size, which are afterwards dried.—Patent completed.

It is again out up into thin leaves or cakes of the required size, which are afterwards dried.—Patent completed.

3178 C. Mayer, Fleet-street, E.C. Tourist's boilles. Dated October 17, 1868.

This relates partly to bottles or flasks to be carried about the person, and also to a metallic stopper of peculiar construction, which may be applied to such bottles. The stopper is constructed in two parts, one of which is firmly fixed in the bottle or other vessel, and forms the seat for a lid or cover, which is hinged or jointed to the said seat. The latter has a circular recess or channel in its face, and the cover is formed with a circular projection or lip to fit into the recess, which is provided with a ring of indiarubber or other suitable elastic material, whereon the projection of the cover is tightly bedded when the stopper is closed. A ring or collar is fitted to turn freely upon the outside of the seat of the stopper, which ring is formed with one, two, or more wedge-shaped projections. The lid or cover is provided with a corresponding number of hooked pieces, which, when the cover is down upon its seat, is just opposite the ends of the inclined projections on the ring. In applying the improved stopper to a tourist's bottle, a tube or nipple is employed in combination with the stopper, which may be readily opened or closed by means of a plug or otherwise. The bottle is filled through the stopper, and then close and secure the same in the manner described.—Patent completed.

3179 D. Wilson, Dundee, N.B. Drag or brake. Dated October 17, 1868.

same in the manner described.—Patent completed.

3179 D. WILSON, Dundee, N.B. Drag or brake. Dated October 17, 1868.

The apparatus is situated to act upon the inner end of the naves of the wheels, and is wholly or partly held in place by a rod at the end next to the rear of the vehicle. It consists of a drag strap, which surrounds the inner hoop of the nave, and through which a screw shaft passes, situated underneath the body of the vehicle. A wheel is placed at the end of the shaft, by which it is revolved and the screw brought into action in the following manner:—As the drag screw is rotated it is forced backwards against the nave of the wheel at the same time that the rear end of the drag is drawn tightly against the opposite side of the nave, so that the nave becomes firmly held thereby, the object being to retard the vehicle in going down a hill and the wheel may be either fixed so as not to revolve when the drag is put on, or it may be allowed to revolve under friction slowly.—Patent completed.

3180 A. DESBONNET, Brussels. Lighting apparatus.

under friction slowly.—Patent completed.

3180 A. DESBONNET, Brussels. Lighting apparatus.
Dated October 17, 1868.

The object of the invention is to construct a protecting vase in such a manner that no shade will be thrown therefrom. This is effected by constructing the body of the lantern of one piece of glass of a circular or other convenient form, and supporting it either by a ring from above or by a light tripod frame below.—Patent abandoned.

or by a light tripod frame below.—Patent abandoned.

3181 W. T. RICHARD and W. C. PAUL, Moorgate-street, E.C. Washing ores. Dated October 17, 1868.
This consists in a trough or receptacle having, by preference, a semicylindrical bottom, provided with a recess or channel at its lowest part for the reception of the amalgam containing the gold or other metal, and from which the amalgam can be drawn off and the gold or other metal separated therefrom. In this trough or receptacle is placed a screw, formed of copper or other metal or metals, or metallic alloy or alloys, arranged in suitable bearings, either vertically, horizontally, or diagonally, as may be desired, and being capable of revolving continuously in one direction, or of having its motion reversed by means of any motive or driving power. The blade of the screw is so mounted upon its spindle or axis that only a space of from lin. to 2in. is left between the several surfaces of which the thread of the screw is composed. A larger extent of surface is thus obtained than in any of the machines for similar purposes in which screws have been employed.—Patent completed.

2182 E. Ludlow, Birmingham. Breech-loading cartridges.

2182 E. LUDLOW, Birmingham. Breech-loading cartridges.
Dated October 17, 1868.
The pulp or wasd of the cartridge is placed outside the metallic head or base containing the gunpowder, and the cup or tube for holding the anvil and percussion cap is made in one piece with the metallic case of the cartridge.

Bettert beneficial. -Patent abandoned.

-ratent abandoned.

3183 H. Bunning, jun., New Cross. Burning liquid combustibles. Dated October 17, 1868.

This relates to a former patent, dated February 5, 1868 (No. 393). The box or retort described in the specification of the former patent is provided with a reservoir at the top, into which the gas or vapour from the zig. zag passage passes, and from which it enters the burner passages, which now are formed as part of the box or retort in place of being separate pipes, as before. These passages run along either side of the box or retort near the bottom, and are perforated for the gas or vapour to escape.—Patent are perforated for the gas or vapour to escape.—Paten abandoned.

abandoned.

3184 F. P. WARREN, Lee, Kent. Cooking apparatus.
Dated October 17, 1868.

This consists in a peculiar combination of steam jacket ovens or cookers with the fireplaces and boilers of cooking ranges. In constructing a range according to this invention, the upper or steam space or spaces of the boiler or boilers communicate by a suitable pipe or opening with a hollow space or casing surrounding the oven or cooker, so that flesh and other food may be cooked without danger of being burnt, or subjected in the process to a more than sufficient heat, and so as also to avoid the absorption of moisture, the boiling or stirring thereof being effected by the steam or vapour given off by the evaporation of the fluids contained in such flesh or other food, without its being placed or coming into contact with water for that being placed or coming into contact with water purpose.—Patent completed.

3185 R. A. GREEN, Strand, W.C. Printed sheets. Dated

3185 R. A. Green, Strand, W.C. Printed sheets. Dated October 17, 1868.

The object is the facilitation of the folding and separation of paper sheets. The papers are punched or perforated with numerous holes along the lines of fold, which have to be afterwards separated. The paper is thus weakened along the lines of perforation and can be more easily folded and torn apart.—Patent completed.

employment of an adjustable expanding and contracting employment of an adjustable expanding and contracting series or rows of guides, through which the warp threads pass as they are delivered on to and received by the beam. These expanding and contracting guides are governed and receive their motion in the following manner:—The rail to which the guides are secured is jointed or otherwise constructed so that it will be capable of causing the guides to give a slightly contracted or expanded direction to the yarn, from the centre of the beam to its outer flanges, the motion being derived through the medium of a spring lever, secured on each side of the machine, which are secured to the ends of the guide rail, their opposite ends beyond their fulcra being provided with bowls, which are brought into foreible contact by means of a spring with the outer surface of the beam flanges.—Patent abandoned.

3187 T. WRIGLEY and J. RICHARRON. Manchester.

3187 T. WRIGLEY and J. RICHARDSON, Manchester.

Looms. Dated October 19, 1863.

This consists in regulating and maintaining at one uniform tension the warp threads of looms as they are delivered from the warp beam by self-acting means.—

Patent completed.

Patent completed.

3188 J. COCKSHOOT, jun., and H. WEATHERILL, Manchester. Carriage axles. Dated October 19, 1868

This consists in forming or constructing the back flange plate of the axle solid, so as to form a component part of the axle, in controlistinction to forming such flange or plate loose, and which in the old construction of mail axle is known as the back plate. This solid flange is formed with a recess or annular space around the axle arm, at the root, on its outer surfaces, towards the nave, the arm of the axle projecting outward from the recess to its termination at the extremity of the nave, where it is enclosed by the sleeve or box and the cap in the ordinary manner. The box or sleeve of the axle is secured in the nave of the wheel.—Patent shandoned.

nave of the wheel.—Patent abandoned.

3189 B. Hunt, Lincoln's Inn. Scisors. (A communication.) Dated October 19, 1808.

This consists in the combination with a pair of scissors of a gauge or measure, by means of which bands or strips of any desired width may be cut from any fabric, paper, or such like material, on a line parallel with the edge of the same. This is accomplished by attaching to one of the blades of a pair of scissors a gauge or measure, which may be secured to the blade in any suitable manner, so that the same may be adjusted laterally at right angles with the blade.—Patent completed.

2100 A. CLARK Chancervlana. Submarine lasterns.

with the blade.—Patent completed.

3190 A. CLARK, Chancery-lane. Submarine lanterns.
(A communication.) Dated october 19, 1868.

This consists in the application to a lantern of an improved means for supplying air, for the purpose of combustion, and also for the protection of the lamp. Also in improved means for supplying the lamp with gas, from a reservoir above the surface of the water. Also in the application of a telescopic attachment for the better observance of the objects to be inspected.—Patent completed. pleted.

pleted.

3191 C. Whitehouse, Bridgtown. Auger. Dated October 19, 1869.

The inventor forms, in the ordinary way, of sand, or other material, parts of a mould which are formed upon a pattern auger. He prefers to make the mould in two parts, but does not limit himself thereto, as, where the form of the auger requires it, the mould may be made in three or more parts. Having put the parts of the mould together and secured them in position he pours into the mould metal, steel, homogeneous iron, or other compound of iron and carbon having the nature of steel, or which, by subsequent treatment, can be converted wholly or superficially into steel. After the solidification of the melted metal, the mould is opened and the auger cast therein is removed therefrom. The auger is afterwards annealed by being heated in contact with the hematite iron ore, or other iron ore of similar composition. The steel or iron of which the auger is made is thereby wholly or partially decarbonized or softened. A number of the cast augers are then shaken in an ordinary shaking tub, by which the particles of sand or iron ore attached to them are removed, and the augers partially brightened. While the auger is still in a soft state the inventor bores, files, or otherwise fashions any part of it which may require a change of form.—Patent completed.

3192 W. E. NEWTON, Chancery-lane. Gun barrels. Dated

3197 W. E. NEWTON, Chancery-lane. Gus. carrets. Dated October 19, 1868.

This relates to a patent, dated May 5, 1868 (No.1475), and consists mainly in the form, arrangement, and mode of using the dies, whereby the several parts of the 1ed hot blank of iron, or other metal, are pressed or moulded into the required form.—Patent completed.

the required form.—Patent completed.

3193 W. H. Howes, Shoreditch. Swing frame glasses,
&c. Dated October 19, 1863.

Instead of employing the ordinary scrows and nuts, or
the cup and ball action now in use, the inventor forms one
part of the movement with a cylindrical stud or pin, which
passes through a corresponding hole or bearing formed in
the other part; and in order to enable the swing frame to
rest in any position to which it may be turned, he employs a washer, formed to fit a square formed on the outer
end of the pin, and passes a screw into the end of the pin,
to force the washer up to the bearing, and at the same
time to bind the bearing to the extent required between
the washer and a shoulder formed on the pin.—Patent
completed.

completed.

3194 W. R. LAKE, Chancery-lane, E.C. Preserving fish.
(A communication.) Dated October 19, 1868.

Fish, either fresh or salted, are taken, and all the skin and bones are removed from them. They are then put into a machine for grating or grinding, this process being continued till the fish is thoroughly broken up. The next process is to desiccate the fish thoroughly. This is done by spreading the mass upon a metal, stone, or other suitable surface, heated by means of steam pipes passing beneath the slab. The fish remains on this slab, and is subjected to a gentle heat until it is well dried and in suitable condition for packing.—Patent completed.

3195 J. RAE, Sydenham. Carts. Dated October 19

tion of paper sheets. The papers are punched or perforated with numerous holes along the lines of fold, which have to be afterwards separated. The paper is thus weakened along the lines of perforation and can be more easily folded and torn apart.—Patent completed.

3186 T. Wrigley and W. E. Yates, Manchester. Beaming the lines of perforation and continuous and perforation and can be more easily folded and torn apart.—Patent completed.

This consists, chiefly, in constructing carts with a tank can be conveniently filled through a manner that it can be conveniently filled through a suitable aperture, and can then be reversed or turned over the part of the cart may be readily and conveniently effected, and for replenishing the warp beams of looms with yarn preparatory to looming. The invention consists in the novel

and its load does not bear on the horse.-Patent com-

and its load does not bear on the horse.—Patent completed.

3196 W.Fitch, Washington, U.S.A. Gun carriages. (A communication.) Dated October 19, 1868.

This consists, first, in a novel method of constructing carriages for ordnance. Second, in a novel construction of the chassiz, and in the securing and arranging of the gun carriage thereon. Third, in providing the carriage and chassiz with devices for operating the gun. And, fourthly, in a novel method of checking the recoil of the gun and its carriage.—Patent completed.

3197 W. Dorr and J. Thornhill. Manchester. Motive power engines. Dated October 20, 1868.

This consists in connecting one or more extra cylinders to the ordinary high pressure cylinder, according to the requirements for the object in hand—that is, the steam exhausted from the first high pressure cylinder is received at the exhausted pressure, and made effective in the second cylinder at a pressure equalling that with which it escapes from the front cylinder, after which, if necessary, the latent power remaining in the steam may be further utilized, and its power made effective by again throwing it into a third cylinder, until the whole effective power of the steam is absorbed; or the steam, after having done service in the two cylinders—that is, with high and low pressure, may be exhausted in the ordinary manner. The fittings and construction of values and other gear is of the ordinary description.—Patent abandoned.

3198 H. A. BONNEVILLE, Parls. Sajety lamps. (A communication.) Dated Geober 20, 1868.

ordinary description.—Patent abandoned.

3198 H. A. BONNEVILLE, Paris. Safety lamps. (A communication.) Dated October 20, 1868.

This relates to the automatical extinguishing of mitners safety lamps, in the first place, when the accumulation of gases inside the lamp, by penetrating the wire gauze, increases the intensity of the flame and caloric, so as to heat the wire gauze red hot, or cause its rupture and the ignition of the gases outside, or when the miner attempts to open the lamp; and, in the second place, to obviate the danger resulting in the rupture or deterioration of the wire gauze when it presents a large surface.—Patent completed.

3199 J. Elge. Manchester. Mules. Dated October 20.

3199 J. ELCE, Manchester. Mules. Dated October 20,

3199 J. Elee, Manchester. Mules. Dated October 20, 1868.

The object of this invention is to regulate the amount of twist put in every stretch of yarn, and to check the momentum of the spindles when the carriage is at the end of its stretch, and when the twist at the head is completed. Another part of the invention consists in an apparatus for regulating the position of the driving straps, on the putting-up and winding-on pulleys. The invention is particularly adapted to the mules for fine spinning, known as box organ mules.—Patent completed.

3200 J. A. FARRAR and R. R. HUNTLEY, Hartlepool. Hatches. Dated October 20, 1868.

It is proposed to make hatches of iron or steel or other metal, and to fasten them to the combings by means of a clamp over the joining of each hatch. The hatches will be made water-tight by having india-rubber, gutta-percha, tarred felt, or leather linings or packings at every joint of the hatches, so that, when the clamps are on, the hatches are perfectly water-tight. On the top of one or more of the hatches or cabins it is proposed to have a manhole, of any height or width, made of iron or steed, or other metal, in a tubular or other shape, with four or more tubes or ventilators attached thereto, or making the manhole a ventilator by enclosing therein a smaller tube with openings.—Patent completed.

3201 G. VOHHT, Cahir, Ireland. Brakes. Dated October 30, 1868.

the manhole a ventilator by enclosing therein a smaller tube with openings.—Patent completed.

2201 G. Voight, Cahir, Ireland. Brake. Dated October 30, 1868.

This consists in continuing the shaft of the ordinary buffer through the cross head of the carriage, to a point near the centre midway between and above the axle. The termination of the buffer shaft slides in a tube supported in bearings, and connected by a centre shaft or rod under the cross bar, with which each carriage is provided. The termination of these shafts or rods is provided with buffers, and the rods themselves are connected by an arrangement of levers with the tube, in which the buffer shafts slide, so that when a forward movement is transmitted to the central shaft or rod, a partial turn is simultaneouly given to the tube. Connected to this tube is a lever that gives, when the tube turns, a rising motion to a vertical sliding bar, having an equi-distant position between the inner peripheries of the carriage wheels, to which rods the brake blocks supported in the ordinary manner are connected, the connection of such rods with the vertical sliding rod being somewhat below their point of connection with the block.—Patent abandoned.

3202 C. LAUENSTEIN, Manchester. Treating parafin.

rou being somewhat below their point of connection with the block.—Patent abandoned.

3202 C. LAUENSTEIN, Manchester. Treating parafin. (A communication). Dated October 20, 1868.

The inventor places in a number of chambers or receptacles, provided internally with spiral steam heating tubes, the solidified paraffin, preparatory to its undergoing the decolourizing process, when the paraffin is melted into a soluble state, in which state he causes it to be agitated, whilst there is added thereto about 10 per cent. of "residue phosphorus," which is the precipitate or coal-like residue left after the process of manufacturing phosphorus is complete. The liquid paraffin is then heated by the heating spiral steam pipe, for the space of about one hour, during which time, the solution becomes thoroughly impregnated with phosphorus coal; after a few hours' rest, the paraffin cools, and the phosphate coal settles partly down, after which the solution is drawn off into another receptacle or vessel.—Patent abandoned.

3203 G. CHAPMAN, Glasgow. Treating secage. Dated

3203 G. CHAPMAN, Glasgow. Treating sewage. Dated October 20, 1868.

This consists in a system, comprising the precipitation of solid matters, by means of lime or other alkaline agent, and the subsequent separation of the ammonia by distillation.—Patent completed.

tion—Patent completed.

3204 E. T. Hughes, Chancery-lane. Tea and coffee pots.
(A communication). Dated October 20, 1868.

This consists, first, in a hard metal body, lined with porcelain or similar material hardened thereon. After being so lined, the body is covered with a softer metal, such as Britannia metal or tin. Second, in the construction of a mineral or earthern pot or body, and covering the exterior surface with suitable metal which may be formed thereon.—Patent completed. -Patent completed.

thereon.—Patent completed.

3205 E. HARRISON, New Haven, U.S.A. Mills. Dated October 20, 1868.

This consists, first, in the arrangement of a bolt cloth or screen around the stones, so that the metal in passing from the stones is thrown against the bolt cloth, the fine or flour portion passing through the cloth to one exit, while the coarse or hull portion is driven out at another exit,

separating the one entirely from the other. Second, in constructing the husk for the runner casing with the supporting frame shaft bearings and sockets for the support of the hopper, and half of the discharge spout, in one and the same piece, whereby a large amount of fitting numerous boits and other expenses of combining the parts is avoided. Third, in casting the husks for the fixed or bed stone, the other half of the discharge spout, feeding spout, and bearing for the shaft, in one and the same piece. Fourth, in staching the hopper to the mill, by forming conical shafts upon the under side of the hopper, placing the said studs into sockets on the runner husk, and pouring metal around the said studs, so as to make a perfect fit and adjustment of the hopper, while the sockets are formed solidly on the husk. Fifth, in the arrangement of the rocker or feeding shoe beneath the mouth of the hopper, so as to be operated by an eccentric on the driving pulley, to vibrate or rock the shoe, to conduct the grain from the hopper to the feeding spout. Sixth, in fixing a band centrally upon the edge of the stones, so that they may be reserved and replaced in their proper positions, the two sides of each being parallel the one to the other; also in securing the stones one to the runner plate, the other to the bed stone casing by means of the said band.—Patent completed.

3206 J. Syrkes and J. Malin, Holborn, W.C. Pulisg-ts composition.

by means of the said band.—Patent completed.

3206 J. SYKES and J. MALIN, Holborn, W.O. Filling-incomposition. Dated October 20, 1868.

The composition intended for filling in the bodies of carriages, is composed of 2lb. of powdered rotten stone, 2oz. of powdered pummice stone, ilb. of white lead, three half pluts of gold size, and one half plut of turpentine, the whole thoroughly mixed together, after which the composition is ready for use.—Patent abandoned.

3207 J. LORKIN, Norwood. Pipes. Dated October 20,

1868.

This consists, first, in applying the light to the tobacco in the pipe at the bottom end thereof, instead of at the top, as usual, the pipe hanging down from the mouth vertically, instead of projecting horizontally, as nearly so, as at present; second, in purifying the smoke emanating from the tabacco, by causing the essential oils therefrom to be deposited on layers of material placed in a receptacle through which the smoke passes; and, third, in purifying the smoke emanating from the tobacco, by causing the essential oils to be extracted therefrom by chemical means.—Patent abandoned. -Patent abandoned.

essential oils to be extracted therefrom by chemical means.—Patent abandoned.

3208 E. T. HUGHES, Chancery-lane. Finishing needles. (A communication). Dated October 20, 1868.

The object of this invention is to polish needles after they have passed through the tempering and scouring process. The first part of the invention relates to mechanism for polishing or finishing the needles, and the second part to a device for separating the needles to present them all in the same position to enter the polishing machine, and the invention consists, first, in one or more polishing rapidly over the surface of a carrying band upon which the needles lie, and combined with a slide which moves transversely across the band, and resting upon the needles, so as to give to the needles a rolling movement as they pass beneath the polishing cylinders, so as to polish the entire surface of the needles. Second, in the arrangement of an inclined plane or table with the proper delivering device, so that as the needles are delivered near the higher end of the inclined table, they, by their own gravitation, will roll down the incline, turning by their own inclination, the head rolling faster than the point, so that the needles, the heads of which lie towards the right, will roll to the left side of the incline, and rice rersa, the heads all lying down the incline.—Patent completed.

\$200 D. and A. Posenel and M. Unguer, Aldgate. \$8ade helders. Dated October 20, 1868.

Patent completed.

3209 D. and A. POSENEL and M. UNGUER, Aldgate.

Shade holders. Dated October 20, 1868.

This consists in a kind of spring catch which projects
through the ear of the holder, and is pushed forward by
means of a coiled spring. When the shade or glass is to
be removed from the holder it will only be necessary to
draw back the spring catch, and the glass can then be
lifted off.—Patent abandoned.

3210 J. F. BRINJES, Whitechapel. Centrifugal machinery. Dated October 20, 1868.

The wire gauge or straining medium is made in the

3210 J. F. Brinjes, Whitechapel. Centrifugal machinery. Dated October 20, 1868.

The wire gauze or straining medium is made in the form of a number of endless bands or cylinders disposed around the drum in such a manner as to enable the endless bands or cylinders to receive a travelling movement of their own upon suitable carrier rollers, or in the case of wire gauze cylinders upon the axis of such cylinders mounted upon the drum. A simple and effective mode of transmitting the independent travelling motion to the endless bands or cylinders of wire gauze is to mount a vertical shaft in suitable bearings outside the main frame, and to impart motion to the second motion shaft by a strap from a cone pulley being mounted on the second motion shaft.—Patent completed.

3211 J. H. JOHNSON, Lincoln's Inn. Boots and shoes. (A

motion shaft.—Patent completed.

3211 J. H. Johnson, Lincoln's Inn. Boots and shoes. (A communication). Dated October 20, 1868.

This consists in so grooving the inner sole of a boot or shoe that it will form an elastic and yielding bearing for the foot; also in so forming such grooves in the counter or heel piece that they will communicate with those of the inner sole, and thus insure a thorough ventilation.—Patent completed.

3212 J. M. BRIERLEY and C. VINE, Bunhill-row, E.C.

3212 J. M. BRIERLEY and C. VINE, Bunhill-row, E.C. Corsets. Dated October 20, 1868.

The busk to one side, or one part of the busk of the stay, corset, or bodice, is provided with a series of movable catches, and the other busk, or other part thereof, is provided with a series of hooks or suitably formed projections adapted to be passed in or on to such catches to hold the parts together.—Patent abandoned.

parts together.—Patent abandoned.

3213 W. MAUDELEY and W. C. RAWLINS, Liverpool.

Furnaces and boilers. Dated October 20, 1868.

This apparatus is placed or constructed within the
furnace, and where a boiler is used it is connected with
the boiler so as to form a part of it. The apparatus has
air pipes, ducts, or spaces passing through the water or
conducting the air between pipes, ducts, or spaces containing water, which air pipes, ducts, or spaces have suitable openings conveying the air over and on to the coals
or fuel, thereby causing complete combustion of the gases
evolved from the burning fuel. The water from the boiler
is admitted to the apparatus and is made to circulate
through it.—Patent completed.

3214 J. Westwood. Bow. Socket totate. Dated Octo-

3214 J. WESTWOOD, Bow. Socket joints, Dated October 20, 1868.
In constructing these improved socket joints the inven-

tor forms a tube of wrought iron or steel, either by bending a plate of such metal and welding its edges together, or by coiling a bar of the same upon a mandrel and then welding it, or by welding together a series of rings or hoops of the required diameter. The interior of the socket or tube is bored or otherwise formed to fit the ends of the sections of the pile or column to be united. The socket may then be heated and tightly shrunk upon one of the sections. The end of the section to be united or coupled to this section is then inserted into the socket, the two ends being preferably made to but together. The inventor then drills holes through both the socket and the pile, into which holes he inserts keys, pins, or boits, which may be riveted or otherwise secured.—Patent completed.

3215 T. FORSTER and J. HEARTFIELD, Thornton Heath. ath gloves. Dated October 20, 1868.

2215 T. FORSTER and J. ILEANIFIED,
Bath gloves. Dated October 20, 1868.
In the manufacture of sponging or bath gloves the inventors employ sheets of india-rubber sponge, which is a porous vulcanized india-rubber. They cut the sheets to suitable forms and then cement the edges of the pieces with india-rubber cement made with benzole. When the cement is dry the pieces are stuck together, and then to make the joint secure they are treated with chloride of sulphur diluted with bisulphide of carbon, and thus the india-rubber films forming the joints are also vulcanized.—Patent completed.

2216 J. STAFFORD, Somers Town. Chimney terminals.

Patent completed.

3216 J. STAPFORD, Somers Town. Chimsey terminals.
Dated October 21, 1868.

This consists in constructing a cylindrical or polygonal tube, on the external surface of the upper end of which are fixed or formed a number of long vertical blades, arranged round the tube, and having a curved transverse section, the convex surface being presented towards the interior of the tube. These blades are of such a width that spaces intervene between the edges of each two, forming long narrow openings, which are covered by a corresponding number of other curved blades or shields, the concave surfaces of which are presented towards the openings, being situated a short distance from the same, while the edges of such shields overlap the hollow surfaces of the first-named blades in such manner as to leave other long narrow openings between such edges notice attracts of the first-mained obliges in such manner as to leave other long narrow openings between such edges of the outer shields, as also between these and the concave surfacer of the inner blades,—Patent abandoned.

3217 J. J. PARKES, Paddington. Stoves. Dated October

21, 1868.

This consists of a cylinder of wrought galvanized iron, which contains a compartment for the reception of dishes for baking and frying, and also of a kettle. The appliance of heat is conducted beneath, around, and above the compartment for baking or frying, and thence beneath and around the kettle.—Patent abandoned.

3219 J. HOLDEN, M.P., Keighley. Combing wool. Dated October 21, 1868.

3219 J. HOLDEN, M.P., Keighley. Combing seed. Dated October 21, 1868.

This relates to means or apparatus for combing wool and other fibres, in which are employed, in connection with the carrying or holding combs, other combs (which are called "nacteur" combs), whose teeth point in the opposite direction to and during part of their motion overlap the carrying combs, and relates to the use therewith of a guard plate, formed with a projecting ledge, in order that it may, whilst bearing against the carrying combs, give support or protection to the points of the "nacteur" combs during the drawing off of the fibre through the teeth of both combs. The plate extends in a direction from the point of tangence of the carrying comb and the drawing-off rollers to the part of the carrying comb at which the long fibres begin to be drawn through the two combs by the drawing rollers, and also to some distance in the opposite direction, and part of it is also formed to act in cutting off or arresting the drawing off from the carrying combs of the longer fibres or top.—Patent completed.

3220 H. CLIFTON, New Bond-street, W. Churns. Dated

pleted.

3220 H. CLIFTON, New Bond-street, W. Churns. Dated October 21, 1868.

This consists in an apparatus in which a stem or plunger, having at its lower end a perforated disc, or series of perforated discs, intended to be worked up and down within a cylindrical or otherwise shaped vessel, is used. The lower portion of the stem or plunger is made hollow, and at a point about midway of its length openings are made in it, leading into the hollow part for the admission of air. As the stem or plunger is raised, the disc or series of discs effect a certain displacement of the milk or cream in the cylindrical or otherwise shaped vessel, to supply the place of which air rushes through the said openings and down the hollow portion of the stem or plunger to the bottom of the churn, whence, partly by the weight of the fluid above it, and partly by the return stroke of the stem or plunger, it is forced through the milk or cream.—Patent completed.

3221 J. H. JOHNSON, Lincoln's Inn, W.C. Bobbiss. (A

or plunger, it is forced through the milk or cream.—Fatent completed.

3221 J. H. JOHNSON, Lincoln's Inn, W.C. Bobbias. (A communication.) Dated October 21, 1868.

This relates to improvements in reels or bobbins, whereby the ordinary wooden reels or bobbins at present in use, which possess the disadvantage of unnecessary weight, are replaced by lighter ones, which the inventor distinguishes by the name of the "Patureau bobbia." This improved bobbin is composed of cardboard, pasteboard, or other fabric capable of being shaped by dies and matrices in a stamping press.—Patent completed.

3222 T. RICHARDS and C. H. CARTER, Birmingham. Extractors. Dated October 21, 1868.

This consists in attaching in a suitable position, upon the forward portion of the body of a breech-loading pistol, a lever of suitable length in the direction of the barrel. This lever is for the purpose of working the extractor. The extractor consists of a slidding bar or blade, formed with a ram piece at one end, for entering the breech-loading chambers, and working horizontally in a suitable grooved recess in the body of the pistol by means of the lever already named.—Patent shandoned.

3223 H. C. E. MALLET, New Bond-street, W. Projectiles.

2223 H. C. E. Maler, New Bond-street, W. Projectiles.
Dated October 21, 1868.
This consists in providing spiral grooves (two or more in number) on the exterior of the hollow or other elongated projectile. The grooves commence at the front end or apex, where they are deepened, diminishing towards the rear end or base and terminating at a short distance therefrom, to prevent any escape of gas in firing, which exerts its whole force on the projectile as usual.—Patent abandoned. abandoned.

3224 E. O. W. WHITEHOUSE, Stoke Newington. Telegraph wires. Dated October 21, 1868.

This consists in the application of an external coating

for the protection of telegraphic wires, which have been previously insulated or coated, either by means of guttapercha, india-rubber, or otherwise, such protecting coating or covering being composed either entirely or in part of compounds or combinations consisting essentially of xyloidine, in conjunction with volatile solvents, oils, resins, tar, asphalte, pigments, or other similar bodies. As an example of the combinations or compounds which are employed, the preparation of a combination of xyloidine with oils, parafflo, pigments, &c., with the employment of a volatile solvent may be given. The gun cotton or xyloidine is, by preference, used in a dry state, but humid gun cotton may be employed.—Patent completed.

3225 H. Warrer, Old Jewry, E.O. Moving machines. for the protection of telegraphic wires, which have b

humid gun cotton may be employed.—Patent completed.

3225 H. WARNER, Old Jewry, E.O. Mowing machines.

Dated October 21, 1868.

To convert a lawn mowing machines into a sweeping machine, the inventor takes from the machine the cutting spindle, which carries the cutting blades set spirally around it, and in its bearings places a spindle fitted with the brushing apparatus, and also fitted with a pinion or pulley at its end, so that the brush spindle may be driven by the same means as was employed for driving the cutting spindle. To again convert the machine into a lawn mowing machine the brushing spindle is taken out and replaced by the cutting spindle.—Patent completed.

2228 C. McMully Sundarland. Protecting from white.

3226 C. McMillan, Sunderland. Protecting from ships. Dated October 21, 1868. The invention consists in a compound of gutta-percha

and resin in equal proportions. These materials are boiled together, using, however, only so much heat as is necessary to admit of the complete mixture of the ingredients, which are stirred and worked together until they are completely incorporated.—Patent completed.

pletely incorporated.—Patent completed.

3227 W. K. Foster, Massachusetts, U.S.A. Carriage wheels. Dated October 21, 1868.

This consists in an arrangement of the ends of the felloe, so as to be supported by the ends of male contracting screws or by plates of metal separate from the nuts of such screws, and placed between the two, and sustained by the screws. Also, in the formation of the halves of the nuts, with recesses in their inner sides, such being as hereinster explained. Also in making the tyre with its inner surface concave transversely to fit to a corresponding convexity of the felloe. Also, in the formation of the block, which is arranged between the ends of the tyre, with a recess on its lower side, in combination with the formation of the outs, with counterparts to enter such recess. Also, in the combination of braces with the tyre, the nuts, and the right and left hand screws thereof.—Patent completed.

3228 F. Benner and R. Wood, New Broad-street, E.C. Capture of whales. (A communication). Dated October 22

1868. This relates to a method of capturing whales and other fish or animals, by the agency of electricity, galvanism, or magnetic electricity, and consists in placing in the boat or whaling vessel, as may be found most convenient, as galvanic battery with its coil and necessary accompaniments, or any other known electrical apparatus, of any required intensity, properly insulated wires being in connection with and passing from the opposite poles or terminals of the said battery or other galvanic apparatus, and inside of or along the line or lines by which the harpoons or other instruments are secured to the boat, the ends of such wires being continued to the points of the harpoons or other instruments, so that the points are in direct communication with the poles of the battery or other galvanic apparatus.—Patent completed.

\$229 B. J. Winslow, Twickenham. Convexing rotary

ratus.—Patent completed.

3229 R. J. Winslow, Twickenham. Conveying rotary motion. Dated October 22, 1868.

This relates to a patent, dated January 25, 1868. Instead of the ratchet pawl and device for lifting the pawl on and off the ratchet, as set forth in the last mentioned letters patent; a flexible band, such as a chain, strap, gutline, or other pliable material is used, one end of which is fastened to the drum, which is described in the specification of the letters patent, or to a loose pulley used to give rotary motion to the axie; the other end of such band afterit has been wound several times round the axie, is attached to a drag, having a movement independent of the drum and axie.—Patent abandoned.

2220 M. A. F. MENNOSE Newstantment. Retiring sectors.

Patent abandoned.

3230 M. A. F. Mennons, Newgate-street. Raising water.
Dated October 22, 1868.

This consists in a cast-from chamber, constructed by the union of castings by bolts. There is a diaphragm of twisted cotton ducts of six or more layers held between two from plates, which are connected with the valve stem, which is provided on its lower end with a nut. There is, also, a pipe for the conveyance of steam into the chamber, and a cast-from base secured to a bowl by bolts. There is a tube, the upper end of which is used as a valve to close against the seat, and a spiral spring is set in this tube. An outlet tube provided with a check valve to prevent rea tube, the upper end of which is used as a valve to close against the seat and a spiral spring is set in this tube. An outlet tube provided with a check valve, to prevent return of water, furnishes a ready outlet for the water. There is a tube leading from one tube to the injector, provided with a valve. The exhaust air and hot water escape leads from hot well, and is provided with a valve

3231 J. RYDER, Manchester. Kilns. Dated October 22,

This consists in placing above the firebars of the different furnaces, a projection or shelving ledge, above which an open space is provided for feeding the fire with fuel.— Patent completed.

C. AKRILL, West Ham. Burning creosote. Dated 22, 1868.

2323 C. Arrill, West Ham. Burning cressole. Dated October 22, 1868.

The apparatus consists of two pipes terminating in nozzles; to one of these pipes steam is admitted, and it issues from the nozzle in the direction in which the flame jet is desired to be thrown, usually horizontally. This steam jet is made to cross the orifice in the nozzle of the other or second pipe, which is placed in close proximity to it at its point of issue, and then the steam jet produces a suction from the nozzle of the other pipe. This pipe is connected with a vessel containing the crossote or liquid to be burnt, and this vessel is usually placed below the nozzle, and the suction draws the liquid from the pipe and causes it to issue from the nozzle in a small stream, and this stream being struck by the steam jet issuing at great velocity at an angle to the direction at which the liquid fuel issues from its nozzle, breaks it up into the fine spray.—Patent abandoned.

3238 G. T. Bouspield, Brixton. Propelling. (A com-

3233 G. T. BOUSFIELD, Brixton. Propelling. (A com-nunication). Dated October 22, 1868. The first improvement is to enable a screw propelling.

arranged at the side of a vessel to receive and discharge the water with facility, although the propeller shaft is connected directly with the steam engine. And it consists in the combination of the hull of the vessel with a shaft ichamber placed at the outside of the vessel and containing the shaft of the screw propeller, and with an overhung screw propeller arranged at the end of the said shaft chamber. The second improvement consists of the combination of the hull of the vessel, exterior shaft chamber, and screw propeller at the rear thereof with a stay to sustain a portion of the weight of the propeller. The third improvement consists of the combination of the said hull of the vessel exterior, shaft chamber, and overhung screw propeller, with a guard above water. The fourth improvement consists of the combination of the said hull of the vessel exterior, shaft chamber, screw propeller, and stay, with a guard, as aforesaid. The fifth improvement consists of the combination of the hull of the vessel exterior, shaft chamber, and screw propeller with two cranks (for receiving the motive power), arranged diametrically (or nearly so) opposite each other so that the momentum of one portion of the propeller engine connected with one crank and moving in one direction, is counterbalanced in whole or in part by the momentum of another portion of the propeller engine connected with the other crank, and moving in the opposite direction. The sixth improvement consists in the combination of the hull of the vessel exterior, shaft chamber, and screw propeller, with pillowheat chamber and screw propeller, with pillowheat chamber and screw propeller, with pillowheat chamber and screw propeller, with the ment consists in the combination of the hull of the vessel exterior, shaft chamber, and screw propeller, with pillow-block frames or brackets of U form, arranged with the closed part of the frame at the exterior of the screw shaft. The seventh improvement has reference especially to the engine for driving the propeller, and consists of the combination of the crank shaft with two steam cylinders of unequal size (the smaller working steam of high pressure and the larger receiving the steam exhausted from the smaller), and with a single four-ported slide valve, which regulates the admission and exhaust of steam for both cylinders.—Patent completed.

cyinders.—Patent completed.

3234 C. D. Abel., Southampton-buildings. Railways. (A communication.) Dated October 22, 1868.

The principal feature of the system of railway forming the subject of the present invention consists in the employment of a continuous timber permanent way of such a width that it is capable of carrying both rails for the rolling stock to run upon. In the application shown, the timber way is represented by a rectangular beam, the ends of which are scarfed so as to form rigid end connections. This timber way is laid either loosely on the surface of the ground with comparatively slight transverse supports at intervals, or it may be fixed down upon piles or uprights; these supports may, on account of the rigid construction of the timber way, be at greater distances apart than those for ordinary railways.—Patent completed.

construction of the timber way, be at greater distances apart than those for ordinary railways.—Patent completed.

2235 T. Carr, Bristol. Disintegrating machinery. Dated October 22, 1868.

This relates to a patent granted to the same inventor, No. 778, and dated March 29, 1859. The present improvements, first, relate to a mode of constructing and arranging the cages of the machine so that increased strength may be obtained, and which admits of a ready application of bars or knives rotating with one or the other of the driving discs, instead of being fixed or stationary, for breaking up such lumps of material as will not pass through the immost cage, and this part of the improvements consists in securing the annular disc to the large disc, or in securing the annular disc to the large disc, or in securing the ring of the outer cage when carrying the annular disc to the large disc by bolts or screw nuts, or other suitable means. Second, the improvements consist in forming the bars of the cages of steel or of cast fron moulded upon cores of wrought iron in "chill," or other moulds, such compound bars being useful when the machine has to operate upon certain hard materials, and also in making such bars, whether compound or otherwise, of oval, square, rhomboid, or other section which will give increased strength to resist lateral percussion. Third, improvements consist in the use of several knives in place of one, as hitherto, for breaking up such lumps of material as will not pass between the bars of the inner cage. These knives may be bolted or otherwise secured together in a ring or rings so as to give strength and support to each other. Fourth, the improvements relate to such arrangement of the cages of a machine as will give larger capacity without increasing the length of the bars of the outer cage, and consists in dishing the large outer disc so that the luner disc may run clear, no that by this means the inner surfaces of the rings and discs are all brought in a line, and the edges are all of the same width a

3236 W. T. Carrington, H. Gieleud, and Z. S. Wesselley, Westminster. Firearms. Dated October 23, 1868. This consists in improved arrangements of breechloading firearms, wherein the opening of the breech for the introduction of the cartridge and the closing of the same subsequently at the same time effects the cocking of the gun ready for firing.—Patent abandoned.

3237 A. B. BERARD, Paris. Converting fron into steel. Dated October 23, 1868.

Dated October 23, 1868.

This relates to a previous patent granted to the same inventor, dated June 20, 1866. To obviate the difficulties that may arise in practice from the employment of a furnace with a double sole plate, in which two operations are combined, and must be conducted, so to speak, simultaneously, the inventor now makes use of a furnace with a single movable sole plate. This sole plate is worked by means of an hydraulic press, and may thus be lowered rapidly, raised or removed at will to be replaced by another.—Patent completed.

3239 T. WALKER, Birmingham. Lever buckle. Date October 23, 18

October 23, 1868.

The buckle or fastening consists of two separate pieces of metal, cut out and formed by press tools in the usual manner, and as well understood. One of these parts has a thin strip of metal left on each of its ends, which is afterwards folded over in such a manner as to form the hinge or joint in which the other part is to work. This other part, which, for distinction, the patentee call the male part, has a pin or axis formed at each of its ends, which takes into the hinge or joint formed in the first-named part, as before described, and works therein.—Patent abandoned. named part, as be Patent abandoned.

Patent abandoned.

3240 J. Birch. Newton Heath. Casting Bessemer isgots.
Dated October 23, 1868.
This consists in a novel arrangement of carriers or conveyers for the moulds, which will facilitate and expedite the process of casting so as to make the same continuous without intermission so long as the metal is prepared and ready to be delivered into the moulds. The invention consists in intersecting the casting pit at any one or more convenient portions of the circle described by the traverse of the crane and ladle, conveying the molten metal by an arrangement of revolving table or tables, the outer circumference of which is constructed so as to support and carry in their revolution a number of ingot moulds, which are capable, through the medium of such revolving turnables or carriers, of being successively brought under the outlet valve of the ladle traversing on the circle around which the first lot of moulds is arranged, thereby enabling a continuous flow of metal to be discharged into the moulds carried by one or more of such intersecting revolving tables.—Patent completed.

3241 W. W. Tonkin, Kingsland. Valves. Dated Oc-

3241 W. W. TONKIN, Kingsland. Valves. Dated Oc-

3241 W. W. TONKIN, Kingsland. Value. Dated October 23, 1863.
This consists in certain methods of constructing pistoms or slide valves, whereby the necessity heretofore existing of maintaining a constant pressure, slways acting in one direction, upon a small area, which is periodically overcome by a pressure acting in an opposite direction upon a larger area, is obviated.—Patent abandoned.

3242 J. DE REDON and T. FACHEUX. Cigars and cigarettes

3242 J. DE REDON and T. FACHEUX. Cigars and cigarettes Dated October 23, 1868.

This relates to improvements in the manufacture of cigars or cigarettes, and more particularly in the wrapper or outer covering, the use of paper in the construction of cigarettes being dispensed with. First, a leaf of tobacco is taken and the stalk and centre rib or fibre is extracted from it; it is then cut rectangular, the length of the cigar or cigarette laying flat on the board, and other substances gummed, pasted, or applied to the edges. The tobacco to form the interior of the cigar is prepared much in the same manuer as in making the ordinary paper cigarettes. It is rolled in the apparatus between the two boards, and when it arrives at the open wrapper, the latter curls itself round the tobacco, and the overlapping edge fastens itself along the surface.—Patent abandoned.

2243 J. Gregson and W. Monk, Lancaster. Looms

3243 J. GREGSON and W. MONK. Lancaster. Looms

3243 J. Greggon and W. Monk, Lancaster. Looms Dated October 23, 1868.

This consists in an improved method of working what is known as an under pick loom, and this is done by a metallic pick motion on each end of the tappet shaft, which motion is obtained by and through a cam on each end of such tappet shaft. These cams act on a bowl working on a stud connected with an horizontal picking shaft, to the ends of which is attached a swivel or universal joint, with catch box for holding the picking stick—Patent completed. completed.

3244 M. SAUTTER, Paris. Preparing wool. (A commu-

3244 M. SAUTTER, Paris. Preparing sool. (A communication.) Dated October 23, 1868.

This consists, first, in saturating the wool with the light vapours obtained from distillation of petroleum, naphtha, or other similar substances; and, second, in supplying oil to the wool in the form of vapour, after it has been properly cleansed, and before it has been converted into fabric. The apparatus consists in a retort, made of any desirable form and size, in which petroleum, naphtha, or other valatile cleaginous substances or compounds are placed, and subjected to the action of heat from any suitable furnace. The retort communicates with chambers or receptacles in which the wool is placed—Patent completed.

3245 M. SAUTTER, Paris. Bamboo fibre. (A communi-

pleted.

3245 M. SAUTTER, Paris. Bamboo fibre. (A communication). Dated October 23, 1808.

In the first place, the knots or joints are removed from the bamboo, which is then split longitudinally into strips by means of sharp-edged instruments arranged for the purpose. After removing the knots or joints, and splitting the bamboo, the lower and tougher portions of the bamboo are separated from the remainder. The bamboo is then boiled in caustic alkali of about 6deg. Beaume, in an open kettle, until the siliceous and gummy matter is softened. This operation requires from six to ten hours, according to the age and quality of the bamboo. The bamboo is pressed while hot for the purpose of expelling the water and so much of the siliceous and resinous matter as may be held in solution or combined with the bamboo. The bamboo is then again boiled in a weak solution of caustic soda for about three hours, and afterwards for about two hours in soap and water, which cleanses and softens the fibre without reducing it to apply condition or impairing its strength, which would be the result if longer boiled in caustic alkali.—Patent completed.

3246 C. B. James, Redditch. Needle-case. Dated Octo-

completed.

3246 C. B. James, Redditch. Needle-cases. Dated October 23, 1868.

Au outer cover, or case and sheath combined, is made of paper, silk, or other suitable material, so as to fold up and close with a tongue piece. From the inner side of the body of this outer case to which it is attached, strips of ribbon, paper, or other suitable material, passes into the sheath, where it is attached to the one side of the same, so that upon the descent of a packet or case of needles into the sheath, the material of the strip, such action tending to bring together and close the parts of the case, whilst the opening out of the same has a contrary effect, the strip being drawn out of the sheath, and consequently propelling or forcing upwards, and partially out of, the sheath, the pocket or case of needles which may be formed of paper, silk, metal, glass, or other suitable material.—Patent completed.

3247 J. Bernard, Strand, W.C. Dressing ore. Dated October 23, 1868.

October 23, 1868.

This relates to an improved stone, ore, or mineral break-ing or crushing machine, and consists of the use and

employment of a series of movable teeth or segments made of steel or other metal placed upon and secured in blocks or rollers containing suitably formed grooves or recesses for the reception of such teeth or segments, and admitting of their ready removal or renewal without involving the removal of the blocks or rollers from their shafts, or the shafts from their bearings. Second, the invention consists in imparting a lateral and differential motion to crushing rollers, which may be effected by means of a cam or eccentric secured to the shaft or shafts on which the rollers are secured, and which is so j. aced and arranged that its differential outline comes in contact with a fixed stud or pin in the course of its revolution, the objectof which motion is to cause the surfaces of such rollers to wear out more evenly. Third, the invention relates to an improved method and means of sizeing or dividing the materials, and consists in combining plain inclined surfaces with inclined perforated plates or sieves, over which the material to be operated upon is passed, and by which a more perfect result is obtained, the whole of the perforated plates, and plain inclined plates, being placed and arranged in a suitable framing common to the entire number employed, and leading into separate divisions or compartments in which the materials are deposited.—Patent completed.

2248 J. Ba668, Holborn. Smelting iron. Dated October 24, 1868.

BAGGS, Holborn. Smelting iron. Dated Octo-

3248 J. Baggs, Holborn. Smelting tron. Dated October 24, 1868.

In charging the furnace, the inventor generally, and by preference, in great measure, excludes and dispenses with the coal or coke usually thought necessary for smelting, and in place thereof he burns in the smelting furnace coal gas, hydrogen, carbonic oxide, or other combustible gas or gases, and also the vapour of petroleum, naphtha, and other hydrocarbons, under pressure and in combination with a blast of hot and cold air. In the case of the inflammable hydrocarbon vapours, the same may be forced into the furnace under the pressure of their own atmospheres, or by means of any suitable mechanical appliances.—Patent completed.

3249 J. Anderson, Ballymacarett, Ireland, Felts. Dated

3249 J. Anderson, Ballymacarett, Ireland, Felis. Dated October 24, 1868.

The ordinary fibrous or capillary substances used in the manufacture of felted materials are employed, but instead of combining the said substances, or causing them to cohere by means of some or one of the bituminous substances heretofore commonly employed for the purpose, they are saturated and combined, or caused to cohere, by means of the native mineral pitch known as asphaltum, specially prepared by purifying and mixing it with suitable tars or oils which have the effect of softening and tempering it. The substances which are applicable for softening and tempering the native mineral pitch known as asphaltum are shale, tar, paraffin, still bottoms, called also paraffin sludge or boghead tar, paraffin tar, Archangel tar, and asphalte oil, and analogous tars and oils.—Patent completed.

3250 J. Spratt, Holborn. Food for animals. Dated

Patent completed.

3250 J. SPRATT, Holborn. Food for animals. Dated October 24, 1868.

This consists in the introduction of the fruit of the date palm (Phonix dactylifera) into any or all of the ingredients to be used as food for horses and cattle. This fruit is to be mixed with flour, or other farinaceous substances, grains or seeds of all kinds, either moist or desiccated, particularly malt, chocolate or cocoa, berries, meat, or its residuum after boiling down (the meat being dispensed with when making up the compound for herbivorous animals), oil cake, sulphur, spices, and any saccharine substance to sweeten such compound.—Patent completed.

3251 B. Hunt, Lincoln's Inn. Power capstans. (A com-

animals), oil cake, sulphur, spices, and any saccharine substance to sweeten such compound.—Patent completed.

3251 B. Hunt, Lincoln's Inn. Power capstans. (A communication). Dated October 24, 1868.

This relates to various improvements in the method of gearing, and other peculiarities in the construction of power capstans.—Patent completed.

3252 R.J. Burn and S. Eyland, Bristol. Construction of conservatories. Dated October 24, 1868.

This consists in the total removal at will of all obstructions to the free growth of plants in conservatories, &c., in the form of glazed coverings, sash bars, or otherwise. This is effected either by removing bodily the whole of the covering portion of the house, by the expanding system, thus leaving the plants free and wholly exposed to the action of light and air, or by the system of shifting entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front covering glass by means of sliding entirely away the front one of which cylinders is engraved or embossed a pattern resembling linen or other similar material.—Patent abandoned.

2254 G. Nurse, Pontymister. Tinning metals. Dated

or other similar material.—Fatent abandoned.

2254 G. Nurse, Pontymister. Tinning metals. Dated
October 24, 1868.

This consists in constructing the apparatus in tinning
metal, in the form of a circular pot with a hollow centre
or otherwise, and with a frame or turntable caused to
rotate in the circular hot air chamber.—Patent completed.

rotate in the circular hot air chamber.—Patent completed.

3255 E. Wimeider, Great James-street, W.C. Blocks for surface printing. Dated October 24, 1868.

The design is drawn on a metal or other surface in ink, containing gum; the surface is then covered with Brunswick black, and afterwards washed, whereby the parts composing the design become bare. Acid is then applied to eat out the design to the required depth. A cast is then taken in metal, which will bear the design in relief; this design is covered with Brunswick black, and acid is then applied to the parts not forming the design.—Patent completed.

Dieted.

3256 A. Giraud, Gray's Inn-road. Separating silver.
Dated October 24, 1868.

The process is commenced by extracting as completely as possible, by any of the ordinary methods, the antimony which may be contained in the lead. Immediately afterwards, the lead is placed in any suitable vessel, but, by preference, in a melting pan, to which an opening is adapted at its base or bottom, in order to allow the fused metal to be run off as required. This melting pan or boiler may be set on an ordinary furnace, but, by preference, the furnace should be provided with a movable grate, which will facilitate the instantaneous extinction or removal of the fire.—Patent completed.

3257 W. Reid, Granton, N.B. Trucks or waggons. Dated

will facilitate the manufacture of the fire.—Patent completed.

3257 W. REID, Granton, N.B. Trucks or waggons. Dated
October 24, 1868.

This consists, first, in constructing the waggons or

trucks with troughs running round them, or across the ends or through the centre, having, by preference, an opening on the outer side for the convenience of supply, such troughs either forming a part of the waggon itself (and having a plug hole to allow the water to run off when it is necessary to clean them out), or being capable of removal therefrom, for cleaning or repairs; also in providing the waggons with racks for hay and straw, and with fixed or movable stalls for keeping the cattle separate when on a journey, and with louvres or other means of ventilation. Second, in erecting at railway stations, sidings or other suitable points on a line of railway a set of support posts or pillars to which are attached either hoisting gear or loading gear, or hooks, by means of which a trough or troughs, a rack or racks, or other receptacle for food may be used to a sufficient height to enable the animals when in the train to drink or feed therefrom.—Patent completed.

in the train to drink or feed therefrom.—Patent completed.

3258 W. G. JAMES, Queen's square. Propelling. Dated October 24, 1868.

It is proposed to mount upon the vessel or carriage to be propelled, a hollow chamber provided with five tubular branches, one of which is centrally placed in the front of the chamber, two are situate at right angles thereto (one on each side), and two more are situate in the rear of the chamber, branching therefrom on each side, at an angle of 60deg. from the longitudinal centre line of the chamber. Each of these branches are open to the atmosphere, and within each there is fitted an airtight piston. The two rear pistons operate as the drivers or propellers, as hereinafter described, whilst the other pair of side pistons serve to compensate the back pressure of the atmosphere against the front piston, when a vacuum is established by means of an air pump or otherwise, inside the said chamber.—Patent abandoned.

3259 S. CLARK, Rye. Decorticating cotton. Dated Octo-

3259 S. CLARK, Rye. Decorticating cotton. Dated Octo-

3259 S. Clark, Rye. Decorticating cotton. Dated October 24, 1863.
A flat board, which first receives the cotton in the pod, is connected to a perforated inclined plate or flat screen, which directs the cotton in the pod into the fixed semi-eyiludrical screen; stones and other like bodies are separated from the cotton pods, whilst they are being fed or moved along the inclined screen. From the end of this flat screen, the cotton in the pod enters into the fixed horizontal semi-cylindrical wire screen, within which rotates a shaft, carring a number of inclined or helical blades, forming a screw, which when rotated, moves the cotton and pods through the screen, the dry leaves, stalks, and such like refuse matter falling through the bottom of the screen, whilst the cotton passes onwards, and is discharged at the end of the said screen into a vertical hopper or shoot, where it encounters a revolving spiked cylinder, working in combination with a fixed inclined surface, also provided with spikes.—Patent completed.

3260 H. E. NEWTON, Chancery-lane. Steam pipes, (A.

provided with spikes,—Patent completed.

3260 H. E. Newton, Chancery-lane. Steam pipes, (A communication). Dated October 24, 1868.

This relates to the kind of pumping engine known as direct and double acting. The main valve is worked by the direct action of steam, admitted and exhausted therefrom, by the action of auxiliary valves, which derive their motion in one direction from the steam piston, and in the other, by the action of the steam and by gravitation.—Patent completed.

3261 H. MAYHEW, Bloomsbury. Button fastening. Dated

3261 H. MAYHEW, Bloomsbury. Button fastening. Dated October 24, 1868.
This consists of a thin piece of metal, bent into the form of a slide, which has a ring at the top. The button shank is passed over one of the prongs of the slide up to the rings, when the sides of the slide or fastener are separated, and the button held in the fabric.—Patent completed.

and the button held in the fabric.—Patent completed.

3262 W. E. GEDGE, Wellington-street, W.C. Glore fastening. (A communication). Dated October 24, 1868.

This is composed of a cord or band fitted to the glove by means of an eyelet hole or plate attached thereto. This cord or band, the two ends of which have been joined, slides at will into a piece of the glove, and is then passed through an eyelet placed at the other side of the glove, a tassel or other suitable object being applied to prevent its return. On this cord or band is placed a movable pivoting or balance catch made slightly conical having a slot through it, and carrying at one of its ends two claws which come down and seize the two cords or bands forming the fastening of the glove. Two holes are pierced in the upper part of this catch, and serve to fix it to one of the cords; the other is passed into the slot, in which it slides freely.—Patent abandoned.

3263 J. L. KIRFFER, Haguenau. Sewing machines. Dated

3263 J. L. KIEPFER, Haguenau. Sewing machines. Dated

3263 J. L. KIRFFER, Haguenai. Secong machines.

October 24, 1868.

There is a notch or slot in the cylinder or cam, which drives the shuttle, so arranged that the shuttle starts to enter the loop as soon as the needle has formed it, and returns before the stitch is tightened up. The shuttle presents the thread to sew at the edges of the holes, the slot or notch in the cylinder or cam feeding the thread slot or notch in the cylinder or cam feeding the thread Two levers are coupled together by a square roller to obtain uniform motion for the presser foot frame. A movable plate covers the shuttle in its slide plate. A screw regulates the to and fro motion, its path being limited by a cam.—Patent abandoned.

# APPLICATIONS FOR LETTERS PATENT

Dated April 26, 1869.

1289 R. Sterne, Cork. Improvements in anchors.

1290 S. Oakman, Boston, Suffolk, Massachusetts, U.S.A.

Improvements in the construction of smelting and other furnaces.

furnaces.

1291 G. Hawxhurst and J. Pollock, San Francisco, California, U.S.A. An improved method of, and means for, preventing the corrosion of steam boilers.

1292 W. Prowett, Loman-street, Southwark, Surrey Improvements in knitting machines.

Dated April 27, 1869.

1293 W. R. Lake, Southampton-buildings, Chancerylane. Improvements in locks.

1294 J. P. Cooper, Bow. Middlesex. Improvements in the construction of auts and bolts.

1295 B. Dobson, Bolton. Certain improvements in carding engines.

carding engines.
1296 The Hon. R. Flower and M. Crowly, Durrow,
Queen's County. Improvements in organs.

1297 J. Cane, Kew, Surrey. Improvements in cases or holders for fusees, commonly known as vesuvians, and other lights, and in fusees or pellets to be used therewith. 1298 J. H. Sams, Aberdeen. Improvements in seed sowing machines and horse hoes, and in combined seed drills and horse hoes. 1299 J. Anderson, New-buildings, Londonderry. Improvements in velocipedes. 1300 R. Marshall, Burnley, Lancashire. Improvements in the construction of wheels for carriages. 1301 H. W. Hart, Fitzroy road, Regent's Park. Improvements in the construction of ovens for baking and cooking.

provements in the construction of ovens for basing and cooking.

1302 T. Aspden, Upper Fountain-street, Leeds, and E. H. Lambert, Adelphi-ouildings, Kirkstall-road, Leeds, Improvements in boots and shoes.

1303 J. H. Simpson, Bolton-street, Piccadilly. Improvements in the means, machinery, or apparatus used in the propulsion of trains by currents of air, parts of said improvements being applicable to other purposes where blowing and exhausting or refrigerating apparatus or pulley arrangements are required.

Dated April 28, 1869.

1304 O. Moseley, Bedford-street, Covent-gafden. Improvements in the construction and manufacture of smoking pipes.

ing pipes. 1305 T. A. Haberkorn and B. Rudolph, Berlin, Prussia.

Ing pipes.

1305 T. A. Haberkorn and B. Rudolph, Berlin, Prussia. Improvements in sewing machines.

1306 I. J. J. Lewis, Manchester. Improvements in the ventilation of hats or other coverings for the head.

1307 J. B. Kroll and A. Froment, Boulevard Sebastopol, Paris. Improvements in percolators for infusing tea, coffee, and other similar beverages.

1308 G. Heyes, Radeliffe, Lancashire, and E. Barlow, Little Lever, Lancashire. Improvements in machinery for winding yarns or threads on bobbins.

1309 N. Voice, Handcross, Sussex. Improvements in eask stands or tilts.

1310 H. A. Bonneville, Sackville-street, Piccadilly. A new and improved means of concentrating the caloric of heated water used for bathing purposes.

1311 J. Pim, Finsbury-circus, City. Improvements in apparatus for ventilating apartments, passages, and other places.

apparatus for ventilating apartments, passages, and other places.

1812 L. Isaac, Elysium Villas, Northumberland Park, Tottenham, Middlesex. Improvements in folding or collapsible tables, stands, and stools.

1813 E. Cooper, Laurence Pountney-lane, City. Improvements in ventilating hats.

1814 T. Bostock, Stone, Staffordshire. An improved application or method of applying elastic fabrics in the manufacture of boots and shoes.

1315 B. B. Forbes, Jermyn-street, Middlesex. Improvements in rigging square-rigged vessels.

1316 J. Frolich, Park Villas, Lonsdale-road, Barnes, Surrey. Improvements in apparatus for generating gas to be used in gas furnaces.

1317 A. Meredith, Newgate-street, City, Improvements in the manufacture of iron and steel.

1318 D. Greig, B. Burton, J. Gozney, and T. Atkinson, Leeds. Improvements in apparatus to be used in cultivating land when steam power is employed.

1319 W. E. Gedge, Wellington-street, Strand. Improvements in the construction of pianofortes and other stringed instruments.

1320 H. Bray and H. Adams, Nottingham. Improvements in graining in oil colours.

1321 W. R. Lake, Southampton-buildings, Chancerylane. Improvements in apparatus for generating and condensing steam, and in furnaces for steam generators and for other purposes.

Dated April 29, 1869.

1322 M. Wilkins, St. James-terrace, Paddington, Middlesex, and J. Clark, South-street, Finsbury, City. Improvements in radiating the axles of railway carriages.

1323 R. Griffith, Aberdeen Park road, Highbury Grange, Islington, Middlesex. Improvements in two-wheel velocipedes and other conveyances.

1325 J. G. F. and G. W. Blow, Commercial-street, Middlesex. Improvements in driving bands for ma-

1324 C. ROSC, POSCA, Steam engines.
1325 J. G. F. and G. W. Blow, Commercial-street,
1325 J. G. F. and G. W. Blow, Commercial-street,
Middlesex. Improvements in driving bands for ma-

Middlesex. Improvements in driving bands for Machinery.

1326 E. Crowe, Middlesborough-on-Tees. Improvements in applying the waste heat from reverberatory furnaces to the generation of steam.

Dated April 30, 1869.

1327 R. Elsdon, Brockham, Betchworth, Surrey. Improvements in the construction of kilns for the manufacture of lime and cement, or for the calcining of ores or other material of a like nature requiring to be calcined.

1328 W. Spence, Quality-court, Chancery-lane. Improvements in the manufacture of felt, and in machines for the purpose.

1329 J. Broadfoot, Glasgow. Improvements in lavatories.

1329 J. Broadfoot, Glasgow. Improvements in lavatories.

1330 J. Jamieson, Oldham, and T. Holt, Rochdale. Improvements in the construction of steam engines.

1331 F. Jackson and T. Corbett, Wigan, Lancashire, Improvements in lubricators for steam engines.

1332 F. Bujeaud, Rue du Gond Angouleme, France, Improvements in apparatus for making bottle envelopes.

1333 A. Sleigh, Lancaster-road, Notting Hill, Middlesex. Improvements in the means of, and mechanism for, obtaining motive power.

1334 F. F. Bigot, Paris. A level with mirror.

1335 J. B. Jefferies, Orwell Works, Ipswich, Suffolk, Improvements in horse rakes.

1336 H. J. Seels, Wainfleet Hall, Lincolnshire. Improvements in harrows.

1337 R. Craig, Newbattle Mills, Dalkeith, Mid Lothian. Improvements in machinery for the manufacture of paper.

Improvements in machinery for the manuscutte of paper.

1338 R. Ward, Newcastle-upon-Tyne. An improved oven or apparatus for baking, heating, or drying.

1339 E. Tutte, West-street, Fareham, Hants. Improvements in the construction of hollow walls.

1340 J. Smith, Stanley-terrace, Rathgar, Dublin. An improved method of communication between passengers in railway trains and the persons in charge of such trains.

Dated May 1, 1869.

1341 T. Greenwood, Leeds. Improvements in machinery for cutting joints for boxes, drawers, and other receptacles of wood.

1342 J. Mackie, St. James'-street, Westminster. An improvement or improvement in lock fast breech-loading frearms.

ing firearms.

1343 J. Wilson, Stockport, Chester. An improvement in the construction of bobbins employed in slubbing, rov-

of cotton for spinning.

1344 W. B. Robins, South Molton-street, Middlesex.

Improvements in hand pumps or syringes, and in other pumps suitable to be used for watering flowers, and for other similar purposes. ther similar purposes. 1345 E. and T. Waltham, Stockwell, Surrey. Improve-

the similar purposes.

1345 E. and T. Waltham, Stockwell, Surrey. Improvements in engines to run on common roads.

1346 J. P. Balm, Halifax, and R. Newton, Providence Mill, near Keighley, Yorkshire. Improvements in worsted spinning frames.

1347 J. B. Blake, Victoria Foundry, Alton, Hants. Improvements in the construction of velocipedes.

1348 G. Ritchie, Folkestone, Kent. Improvements in the construction of stop hinges.

1349 W. Broughton, South-street, Finsbury Market, Middlesex, and T. Stevens, Glasgow. Improvements in cooking ranges and other fireplaces, and in apparatus for carrying and turning cooking spits, parts of the said apparatus being also applicable for turning ventilators and other appliances.

1350 J. Conway, Stone Stairs, Broad-street, Ratcliffe, Stepney, Middlesex. The improvement in forge fires.

1351 R. Saunders, Croydon, Surrey. Improvements in cable stoppers and controllers.

Dated May 3, 1869.

1352 C. T. Liernur, Frankfort-on-the-Maine, Prussia. Improvements in the daily inodorous removal, and agricultural utilization, of human excrements, known as Liernur's pneumatic sewerage system.

1353 P. Barry, Lombard-street, City. An improved mode of, and means for, delivering sheets of paper to the feeding apparatus of a printing machine.

1354 J. Shackleton, Bradford, Yorkshire. Improvements in utilizing the exhaust steam from steam engines, and in apparatus for regulating the discharge or flow thereof.

thereof.

1355 S. H. Hodges, Bristol. Improvements in the construction of apparatus for the manufacture of heels for boots and shoes.

1356 H. Williams, Portwood-street, Liverpool. Improvements in velocipedes.

1357 J. B. Nimmo, North Bank-street, Edinburgh Improved lever compensation door and gate spring or closer.

Improved lever compensation door and gate spining or closer.

1358 B. Hunt, Serie-street, Lincoln's Inn. Improvements in spinning hemp, flax, and other fibrous substances, and in apparatus to be employed therefor.

1359 D. P. Wright and C. Butler, Birmingham. Certain improvements in lamps for burning paraffin and other hydrocarbon oils.

1360 F. W. Kaselowsky, Bielefield, Prussia. Improved machinery for separating the woody part from the fibre of flax, hemp, jute, or other fibrous substances of the same nature.

1361 P. Southern, Top Lock, Aspull, near Wigan, Lancashire. Improvements in furnaces.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office MoneyOrder should be sent, payable to ROBERTSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.O., to whom all communications upon the subject should be addressed.

Science and Art.—A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brooches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[Advt.]

### IRONMONGERS' JOURNAL

BRITISH METAL WARES REVIEW.

A Monthly Organ of Intelligence for Ironmongers and Hardwaremen.

Published at Birmingham on the 15th of every month. Annua Subscription 5s., in Advance. Specimen Copy, 6d. Subscriptions and Advertisements to be addressed to

# FRANK H. RYLAND,

55, UNION PASSAGE, BIRMINGHAM.

55, UNION PASSAGE, BIRMINGHAM.

"The IRONMORER' JOURNAL, published at Birmingham, present decidedly the finest typographical appearance of all the papers we get; and as it is devoted to subjects connected with the hardware rade, and published at the great hardware centre of Great Birtain, it would be useful to importers and large dealers. It is conducted with enterprise and care."—" Iron Age" (New York, U.S.)

"This admirably conducted periodical constitutes a British Metal Wares Review, and is a monthly organ of intelligence for Ironmongers and Hardwarennen. It deals with all subjects interesting to these connected with the great industries to which it is devoted. The information is full, and so far as we have been able to test it accurate. It is beautifully printed en toned paper, and, when the subjects require it, well and tastefully illustrated. Such a periodical cannot fall of being of great service, and we wish it every success."—

LONDON: FRIDAY, MAY 14, 1869.

# APPLICATION OF LIQUID FUEL TO METALLURGY.

THE advantages of liquid fuel, when properly used, over coal for steam purposes have long since been fully demonstrated, and they stand unquestioned. Hitherto, the endeavours to utilize mineral oils have been chiefly confined to the furnaces of boilers; but now we have another eminently successful application of the oil furnace to metallurgical purposes. Our readers can hardly have forgotten the successful trips of the "Retriever," a steam ship of 500 tons burthen, which was fitted up on the system of oil furnace invented by Mr. Dorsett, of 12. London-street, City. This system— 12, London-street, City. This system—which will be found fully described in the which will be found fully described in the numbers of our journal stated at foot\*—consists in burning in the furnace the vapour of creosote, which is produced in an auxiliary boiler. The creosote is, in effect, distilled over, and the products of distillation are burned from jets beneath the steam boiler. Having established the success of the principal in one direction. Mr. Dorsett consisted ciple in one direction, Mr. Dorsett conceived ciple in one direction, Mr. Dorsett conceived the idea of utilizing it in another—that of heating iron plates for bending. The idea was first put into execution about four months since, when Mr. Dorsett obtained permission to apply his system of burning liquid fuel to a plate-bending furnace in Woolwich Dockyard. This was for plates of the ordinary thicknesses used in iron ship-building, and the results were so satisfactory that the authorities directed the principle to be applied to an ordinary plate-bending furnace and to an armour-plate furnace in Chatham Dockyard. It is to the latter of these we wish to direct special attention, as being a great triumph of the Dorsett prin-ciple of burning liquid fuel. On this day week, we were present at some trials with this furnace, which conclusively establish the superiority of the liquid fuel over the coal furnace.

Under ordinary circumstances, the armour-plate bending furnace is lighted from four to five hours before the plate is placed in it. The time occupied in heating the plate for bending depends upon its thickness—one hour per inch of thickness being allowed. Taking, then, a 6-inch plate—as upon the present occasion-we get from ten to eleven hours from the time of starting before the plate is ready for bending. Let us now see what the liquid fuel will do. Upon our visit to Chatham, the cold furnace was lighted, and after an hour was deemed sufficiently heated. A 6-inch armour plate, 7ft. 6in. long by 3ft. wide, was then consigned to the furnace, and after an hour and a-half was drawn out thoroughly heated and ready for bending. Thus, in two hours and a-half we have the work of ten or eleven hours completely and satisfactorily performed. Nor is this all; the advantages of the system do not stop here. The plate was remarkably free from scale, which can only be accounted for by the absence of the deteriorating influence of the products of combustion in the ordinary furnace. Another valuable result arises from this same cause; thinner plates, when heated by liquid fuel and bent double, show no signs of cracking, as they usually do when they have been heated in the coal furnace. This important feature is reckoned to save ten shillings per ton on the metal, which amount it would lose in value by deterioration under the

\* See the MECHANICS' MAGAZINE for October 16 and 30 and November 6, 1868.

The vaordinary method of treatment. porized creosote is supplied to the furnace under notice from the generator by six jets, which are led in through small openings, by which means also just a sufficient quantity of atmospheric air is admitted to support combustion. This method of supplying the heat also offers another advantage; it can be applied to the whole or any portion of the plate. Thus, if a plate requires to be bent at one end only, then the heat is directed to that part. Further, the rate at which the metal is heated can be regulated to a nicety by either increasing or diminishing the num-

by either increasing or diminishing the number of jets. The consumption of oil at Chatham is 108 gallons per furnace per day.

Close beside the armour-plate furnace is another one for heating thinner plates, and which has been regularly at work for some time past. It is heated by four jets, and is supplied from the same generator as the larger one, and which is placed between the On the occasion of our visit some half-inch plates were being heated and bent to various templates. The average time occupied in heating was seven minutes; with the ordinary furnace it takes from twelve to the ordinary furnace it takes from twelve to fifteen minutes for each plate. As already stated, the heating of the 6-inch plate was only experimental and preparatory to a regular course of practical work which is about to commence. But it was an eminently successful experiment, and, moreover, was not the first made in the same furnace. The plate in question had been through the same process three times previously, although its clean, smooth surface would not have led to that supposition, for it had the appearance of having had nothing done to it since it left The future work of the furnace will consist in heating the armour-plates for bending for the "Sultan," a fine vessel of 5,226 tons burthen, now constructing close by the shop in which the Dorsett furnace is In this furnace we have another practical evidence of the value of liquid fuel when utilized in the form of vapour. In its working we have some of the most remarkable and unlooked-for results, which, while they fully satisfy us for the present, only lead us to expect further and even more important improvements in the application of the system. We cannot affect to ignore the labours of others in utilizing liquid fuel; but while giving them every credit for their ingenuity and perseverance, we are bound to regard Mr.
Dorsett as the successful exponent of the
principle. It was he who first demonstrated the practicability of running a vessel of 500 tons burthen by means of liquid fuel, and it was he who has now succeeded in advancing the science of metallurgy in an important degree, in a way which will prove highly beneficial to the iron industries of the world.

# STREET BRIDGES.

THE report of the Registrar-General for 1868 states that 203 persons were killed by horses and vehicles in the streets of London during last year. In a recent week, five lives were lost in the same way, or at the rate of 260 per annum! It needs scarcely be said that this is a state of things that calls loudly for a remedy, if remedy be possible. It certainly demands that the question should be asked and fully considered, and honestly answered—has all been done that may and ought to be done to abate this frightful sacrifice of human life?

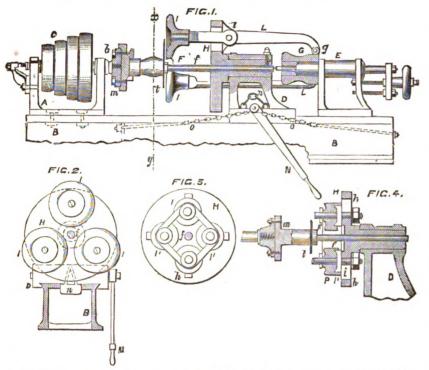

Let us inquire what has been done or attempted, on behalf of foot passengers, to protect their lives and limbs in passing across intersecting thoroughfares. It is well to state

trian who has the courage to make the attempt scarcely demands advocate or protector. But it is only a small proportion of the foot passengers in the streets of London that have the cool nerve, the keen eye, and the sure foot needed to attempt this feat, and those who can accomplish it safely may very well be trusted to get across at St. Paul's Churchyard corners, at the bottom of Ludgate-hill, or wherever else the footpath is continued across the carriage way. Such protection and facilities for moving about London is needed—we venture to think de-manded—on behalf of the aged, the timid, manded—on benair of the aged, the timid, and the infirm, many of whom street crossings almost paralyze with abject terror, as may be witnessed almost at any hour of the day during the busiest time at the crossings to which we have just referred. The palliatives of the danger are—1st. The regulation of the traffic by the police, who discharge their onerous and important duties in this matter in the most admirable manner. The streets would, in fact, be in a constant state of im-passable block for vehicles, horses, and pedestrians, but for the valuable services of the police. 2nd. Next, there is the mitigation of police. 2nd. Next, there is the mitigation of the danger by the provision of "refuges" in the middle of intersecting streets; an expedient attended necessarily by the serious disadvantage of contracting the space for vehicles just at the points where it ought to be widest. 3rd. We suppose the experimental semaphore signal pillar at Westminster may be regarded as an expedient to abate "the perils of the streets." It is doubtful, from what we have seen of the working of the street semaphore, whether it can ever be more than an auxiliary to the living police-men. Practically, the constables continue to be the regulators at the junction of Parlia-ment-street with Bridge-street, and, in so far as the number of men on duty is concerned, the semaphore appears to require an extra man to work it, in addition to the policemen stationed at the corners of the streets.

The only other alternatives that can be adopted to secure absolute safety to foot passengers-and these have been under discussion for many years—are subways or bridges connecting the foot pavements at street cross-To the subways the objections apply that they would require constant watching or would certainly become intolerable nuisances; that they would otherwise be the resort of bad characters, and facilitate the escape of culprits; and that they would require artificial lighting day and night. To the bridges it is objected that they would either involve a heavy cost in the purchase of valuable frontage property for the stairs, or would obstruct the foot walks to the hindrance of those who would not use the bridges; and objections, on æsthetical grounds, have also been urged, that they would disfigure the streets. We venture to think that if street bridges were provided having easy ascents, very many persons would regard them as a great boon, and would gladly use them. We learn that a would regard them as a great boon, and would gladly use them. We learn that a design for iron or steel bridges for street crossings, by Mr. T. Ivison, C.E., is at present under the consideration of the Court of Common Council of the City of London. We are informed that the design has been spoken of in highly commendatory terms by aminent angineers as structurally, abundantly eminent engineers as, structurally, abundantly strong, and, artistically, fitted to prove highly ornamental to the thoroughfares in which the bridges may be erected. It is proposed to have two pairs of stairs at each corner of the intersecting streets. These stairs approach each other by curves, and, joining at the top of the rise, form the end of the bridge way. The bridge ways cross diaintersecting thoroughfares. It is well to state the limitation as to intersecting streets; to cross Cheapside, Fleet-street, Gracechurch-street, or other crowded thoroughfares, during the high tide of vehicular traffic, must, we high tide of vehicular traffic, must, we are constrained to admit, be at the passenger's own risk to a great extent. The pedes-

Digitized by Google

#### FORCHASING. MACHINE

allow a continuous stream of passengers to pass in each direction. The width of the pass in each direction. The width of the bridge between the stair landings is calculated and adjusted to the number of passengers that may ascend by the several stairs, and gives room for easy passage, but none for lounging on the bridge, which would of course require to be kept by the police. The clear headway for carriages would be 18ft. The curved form of . Le stairs would obviate an insuperable objection that ladies might otherwise have to using the crossings, and would probably secure for them the decided favour of the ladies, by whom it might be expected they would be freely used.

We venture to think that if the design

before the Court of Common Council may fairly lay claim to the qualities of strength and beauty, that body owes it to the public considering the dangerously crowded character of the street traffic, an evil that is daily on the increase—to test the convenience of these bridges by an experimental structure, say, at the intersection of Gracechurch-street with Fenchurch-street, at one of the corners of St. Paul's Churchyard, at King-street, Cheapside, or at any one of a dozen places that might be named at which there is a constant stream of traffic, and where the span is comparatively narrow, so that the smaller cost would be involved in the experiment.

Since the above was written, we have been informed that the subject has been further considered by the Committee of the Court of Common Council, to which the matter was referred, and that Mr. Ivison has received official instructions to prepare the model of a street bridge, adapted to the crossing at the street bridge, adapted to the crossing at the bottom of Fleet-street and Ludgate-hill, where they intersect Bridge-street and Farringdon-street. The Council and the public will apprehend much more readily the character of the proposed construction from the model than is possible from the drawing.

# MACHINE FOR CHASING AND EMBOSSING METALS.

T is impossible but that a man who, from day to day, is engaged in working the same machine, should be able to detect its weak points, and become conscious, by the unfailing test of actual experience, of its deficiencies. Although it is commonly agreed that when a

fault is known and recognized, it is half amended, yet this does not hold good in mechanical engineering. On the contrary, there is scarcely a single machine that has not several faults, and yet the inventors themselves, and many others, have been for years endeavouring to remedy them without success. To be able to perceive the imperfection of any machine is comparatively a simple, feat to being capable of rendering it more efficient, or, in fact, supplying the essential characteristic in which it may be Numerous as are the continual new wanting. patents taken out for improvements in the details of mechanical appliances, their number would be still greater if every workman who experienced a defect were able to invent a remedy. In the accompanying illustrations is represented a machine for stamping, chasing, and embossing metals, which has been recently patented by M. Grünenburger, of Owing to the special contrivances Nouzon. adopted in its construction, it is capable of performing these operations not only with a greater facility than other similar machines, but effects a saving in the items of labour and manipulation.

The principal feature consists in furnishing the head of the lathe with a mandril, the exterior of which corresponds with the shape of the object to be stamped. In the axis is placed a piece of metal terminated by a kind of plug or buffer, which forces the sheet of metal used in the operation against the end of the mandril. The chasing lathe is shown mounted upon its frame in the longitudinal section in fig. 1, while a cross section, taken through the line x y, is represented in fig. 2. Upon the frame B, which is similar to that of an ordinary lathe, is mounted the puppet A, carrying the cone C. To the frame is also attached the slide D, the puppet E, and the socket G. One end of the shaft or axis of the cone C, has a thread cut on it, to receive a small plate upon which is fixed the mandril plate m. The plate has the same external shape as that required to be given to the metal under operation. The mandril consists of six pieces or more, according to circumstances, which are arranged around a central nave slightly conical in form, and maintained in their places by means of the ring b and an adjusting thumb screw. By loosening the screw, and removing the mandril, with the exception of the central conical part, which in diameter.

is in one piece with the plate, the object can be withdrawn at once.

In the axis of the mandril is placed the buffer F, attached to the rod f, working in the slide D. This buffer compresses the sheet of metal t, between itself and the end of the mandril m, the pressure being exerted by the central rod of the puppet E. The slide D carries the upright H, which is cast with three lugs l, to serve as centres for the levers L, which carry at one extremity the embossing rollers I, which force the metal to take the contours of the mandril when the slide D is put in motion. This movement is effected by manipulating the lever N, to the axis of which is attached the nut n, around which the chains O are placed. By changing the component pieces of the mandril and corresponding socket G, upon which the small roller g moves, any description of metallic chasing or embossing can be performed. In figs. 3 and 4 a modification of the above arrangement is represented, where four rollers I are exhibited. They are adapted for the embossing of cylindrical objects, and the distance between them is regulated by altering the position of their axes i, in their bearings h. They are held firmly in their places by the ring P. If it be required to pierce the objects manufactured with a central hole, the mandril m can be furnished with a point, fitting into a corresponding opening in the buffer F. All objects executed in copper can be successfully treated when cold, but where iron is the metal used, it depends upon the thickness whether it must be heated or not.

# BLACK SEA CABLES.

THE cables to be submerged in the Black
Sea are by this time Sea are by this time completed, and in a few weeks will be on their way to their submarine destination. In order to avoid the mountainous range of the Caucasus, the Indo-European Telegraph Company (the progress of whose works we lately alluded to) determined to lay a cable from the Crimea to a point on the Asiatic shores of the Black Sea, considering that the difficulties of the submarine would be far less than those of the mountainous route, the probability of inter ruption in the former being much less. The orginal cable route was not adhered to, but a shorter route finally settled upon, the length of cable being 100 miles, starting from a point near Djulfa, on the Black Sea, and landing at Suchum Kalé. The second section of cable is that for the Straits of Kertch, a threewire cable of heavy proportions. The insulated core of the Black Sea cable is similar to that of the cables that are generally known -a stranded conductor surrounded by coats of gutta-percha. The insulated conductors in this cable are three, each weighing 273lb. per nautical mile (copper, 107lb. per mile; gutta-percha, 166lb. per mile). It is in the materials specially used for strengthening and preserving the "core" that this cable so essentially differs from all others. Its construction is similar in every respect to some small cables made by Messrs. Siemens Brothers, for the French Government, some few years ago, and laid in the Mediterranean, on the place designed and specially advocated by Mr. C. W. Siemens. The present cable has been manufactured at the works at Charlton. In the ordinary system of cable making, the core is protected with a serving of hemp, and sheathed externally for extra protection, and for strength, with a helical covering of iron wires, the number and size of which depending upon the size of the core and the locality for which the cable is intended. In Siemens' cable, however, the main strength rests in a large serving of best Italian hemp, giving it the character of a rope; this serving is protected (adding, at the same time, some strength to the cable), by a sheathing, laid helically, of strips of flat copper of about  $\frac{3}{4}$ in.

The copper selected is of the best quality, and arrives in the shape of long broad sheets. These sheets are first passed through the shearing machine, where, by means of knives placed above and below, the entire sheet, as it passes through, is divided throughout its breadth into equal narrow strips of the breadth required for sheathing the cable. On coming away from the shearing machine the strips are wound on small bobbins. If a strip of metal or anything be attempted to be wound round a long cylinder, it will in-fallibly bulge up and tend towards the trumpet form, and in order to prevent such a result happening to the copper strip in the cable, it undergoes a process termed "rabitting." Each strip before going to the sheathing machine passes through this operation, which consists in slightly bending its edge and grooving its centre. The bobbins prepared copper are then taken to the closing machine for the final process, but we must first describe the ordinary covering with hemp.

The three insulated wires of the Black Sea cable are served together and wormed, the worming consisting of a number of strands of best Italian hemp. In compound cables some difficulty is experienced (unless special marking be adopted) of knowing one wire from another. In the present cable, Mr. Siemens adopts the simple but excellent plan of passing along with one of the hemp wormings a white tape, which serves as a zero line. After being twisted together and wormed, the core receives its strengthening protection by being served with two servings of best Italian hemp. Each serving consists of about twenty compound strands of hemp, served under tension, and with a very short lay. The second serving is in the reverse direction to the first. After this serving, the cable receives its external protection of copper sheathing, which consists of four strips of the prepared copper, laid helically, one strip overlapping the other for one half its breadth. In consequence of the strip being previously prepared, the cable comes outnice and smooth, and coils most readily, being exceedingly exceedingly and easily managed. The strips of copper are soldered into continuous lengths, care being taken that no two joints be allowed within a certain distance of each other.

In the manufacture of these cables, the whole process goes on at the same time, and really in the same machine. By the application of the same power, the wires are stranded and wormed, served, and finally sheathed in one continuous machine. Usually, these operations are separate and distinct; the core is commonly stranded, wormed, and served in one machine, and afterwards finally sheathed. At Charlton, these several operations are conducted on the same machine (or, rather, combination of machines) at the same time. Where space is an object, this plan is undoubtedly advantageous; but otherwise where there is plenty of room, we cannot but think that time must be lost. Anything required to be done to any one part necessitates a stoppage of the whole. The jointing of the gutta-percha wire, the replacing a hemp bobbin, or the jointing of an external wire, each must stop the whole machine; whereas, in separate machines, only one is

been engaged for the work, and fitted up with the necessary watertight iron tanks, which are three in number. They are placed in the fore and main holds, the forward containing the Kertch cable; the main, the Black Sea (copper sheathed) cable. Over the fore tank, when the cable is in, will be placed a second tank to receive the shows and of the Black Sea cable. The the shore ends of the Black Sea cable. The paying out and picking up machinery, with engines, have been constructed by Messrs. Easton and Amos, and are placed at the stem of the vessel, the paying-out machine being used, if required, for picking up. This ma-chine is so arranged that at any moment it can be stopped and the engine attached to it, in order that the cable may be drawn in to any distance. The engine is supplied with steam either from the main boiler or the donkey. There are some special features of interest relative to the friction brake and the dynamometer, which call for attention, but we regret that want of space compels us to postpone our notice of them to a future occasion.

It is expected that the vessel will leave at the end of this month or the beginning of the next. Mr. C. W. Siemens goes out with the vessel, and will superintend the operations in connection with laying the cable; and we trust that the expedition will meet with all success—completing successfully an important section in the system of the Indo-European Telegraph.

# METEOROLOGICAL RESEARCH BY AID OF THE ELECTRIC TELE-GRAPH.

No. II.

N resuming our consideration of the above subject, subject, we will first notice Captain Maury's opinion, given by letter, dated December 15, 1860, to the British Commission on Lighthouses. The meteorological information which it would be most desirable to transmit to passing ships, as well as to ships in the offing and ports, supposing the telegraph extended to certain lighthouses, would be that relating to the coming storm, and the approach of good weather after it, with the direction of the wind, &c.; and he proceeds

There occurs annually in British waters, and within signal distance of British shores, an amount of shipwreck and disaster that is truly appalling. A single storm has been known to wreck or damage several hundred sail, and to destroy many lives. Now, most of the storms of this class modern research has shown to have their line of march. Taking up this line at one place, one of these storms may, and not unfrequently does, occupy one, two, three, or more days in traversing the region hay, and not unirequently does occupy one, two, three, or more days in traversing the region over which the indefatigable Chief of the Meteorological Department of the Board of Trade has posted his sentinels upon the weather, as his telegraphic ob-whereas, in separate machines, only one is stopped at a time.

The specific gravity of the copper sheathed cable is 1.6; its weight a little over 2 tons; and, although apparently showing but slight signs of strength, its breaking strain is considerably more than would be imagined, amounting to nearly 5 tons. The shore ends are of heavy iron wires, and of the usual construction. The Kertch cable is also an iron covered cable, but the core consists of three wires insulated with Hooper's material. The iron wires are protected externally with a serving of tarred hemp, and the whole weighs about 12 tons to the mile. The steamer "Hull" has

coast of Europe; she is the great commercial centre. All vessels sailing abroad on the Atlantic from any of the continental ports between Ushant and the White Sea pass her offings on the outward voyage and take departure from her cliffs. On the homeward voyage the first landmark is some British lighthouse, headland, or islet. Moreover, those islands, unlike the coasts of any other of the great maritime nations, present in every gale that visits them a lee

Captain Maury further said, in 1861, vide "Nautical Monograms, No. 2," that the electric telegraph placed it in our power "to give warning of the coming storm to the shipping in ports, to the shipping in the offings, to farmers on shore, to travellers, and, in fact, to all who are concerned in a foreknowledge of the weather—and that's everybody."

The practicability of giving forewarning of

great storms to the coasts of the British Isles and of the neighbouring nations having been proved, Admiral Fitzroy thought that the data with which he was daily furnished were sufficient for the purpose of forewarning of subordinate changes of weather, which fore-knowledge expressed merely as an opinion would, he imagined, be useful to the public generally. These opinions, derived from generally. consideration of actual recent observations, he termed forecasts; and in August, 1861, he commenced to send them, with the weather tables, to the newspapers. At the outset, this ambitious experiment was conducted under various tentative arrangements-it would seem, to gain experience—which, however, considerably marred and detracted from their value, because this instability showed a source of weakness, and deprived them of the sustained attention of thoughtful and inquisitive people. It was upwards of two years before they were settled into a consistent method. The evident absence of precision which thus for so long characterized the forecasts no doubt influenced the Board of Trade to appeal to the Royal Society as they did by letter dated February 27, 1863. The Board stated their reluctance

In any way to impede the progress of a system which may prove to be of practical value in saving life and property, but at the same time they wish to be satisfied that the knowledge of the causes and preceding indications of the phenomena of the atmosphere the property of the property sphere has arrived at such a perfection as to render advisable a continued and increased expenditure on weather forecasts for the guidance of the masters of merchant vessels and others carrying on maritime pursuits on the coasts of the United Kingdom.

And their Lordships asked the Royal Society "whether the science of meteorology is now in such a state as to admit of a permanent reliable system of storm signals and daily weather forecasts." The President and Council of the Royal Society, in their reply, dated March 23, 1863, stated:-

With respect to the public importance and the practical success of the superadded branch of the duties of the Meteorological Office, the Board of Trade have opportunities of judging which the Royal Society have not; but the president and council have noticed with great pleasure, in the replies to inquiries circulated by the Board of Trade to the various ports of the kingdom, that three only of the replies are unfavourable, whilst those that are decidedly favourable amount to no less than

In the forewarnings of storms much must, as yet, and onbeddy be viewed as, in a great measure, ten-tative; but there is one class of cases on which such premonitory information is entitled to be regarded as resting on more assured scientific relations. Admiral Fitzroy considers that he has satisfactorily established the occasional occurrence of storms of a cyclonic character of very limited diameter, not much exceeding, perhaps, that of the British much exceeding, perhaps, that of the British Islands themselves, and originating in their vicinity. Islands themselves, and originating in their vicinity. The practice of forewarning is specially suited to such storms. They are characterised by great violence and by frequent and rapid changes in the direction of the wind. The key to their comprehension is supplied by the telegraphic reports which convey to the Central Office a knowledge of the various simultaneous directions of the wind in different localities; and when once comprehended different localities: and when once comprehended they are particularly suited for forewarning, inas-much as, in its general course, the advance of the cyclone is steady in direction and moderate in

With respect to the "forecasts of the state of the

weather" which are published in the newspapers, the president and council learn from Admiral Fitzroy that they really occasion no cost to Government, and scarcely fall, therefore, within the questions submitted for reply; moreover, the president and council have no data whereon to rest a conclusion in regard to the degree of reliance to which these last-named forecasts may be entitled.\*

Under circumstances of much official opposition, the storm warnings and forecasts of weather were suffered to continue. With the seafaring community, the storm warnings continued to gain favour, and much attention was paid to them. Many scientific men never admired the weathercasts; nevertheless, they were much esteemed by the public. They had now been reduced to greater clearness of statement, seemed simple in conception, and exhibited promise of improving into very reliable announcements of the broad features of impending weather from one to two days in advance. Admiral Fitzroy gained unbounded publicity and popularity. He was conscious that he was working out a practical utilization of meteorology unattempted previously on so sound a basis, and he gave unremitting attention to the duties of his post, till at length his constitution and his reason gave way, and he ended life by his own hand on April 30, 1865.

At the lamented death of Admiral Fitzroy, the weathercasts were at once discontinued by the Board of Trade, and they appointed a committee to inquire into the working of the whole system of meteorological telegraphy. The report of this committee condemned the forecasts, and strove to nullify the utility of the storm warnings, which, however, were continued very successfully by Mr. T. H. Babington, the admiral's chief assistant, until December, 1866, when the Board of Trade announced by circular their suspension, be-cause the President and Council of the Royal Society, whom the Board of Trade had consulted upon the subject of the report, were of opinion "that at present these warnings are founded on rules mainly empirical." So earnest, however, were the remonstrances of the public against this step, and so clamorous was the seafaring community for their resumption, that the Board of Trade felt compelled to induce the office, now placed under the management of the Royal Society, to undertake to give the seaports "telegraphic weather information," the euphonious disguise under which they eventually undertook to do what they had in the first instance refused to attempt to do. Accordingly, the storm warnings, in the modified form, were renewed at the beginning of 1868, after they had been in abeyance upwards of a year, and they are still issued on the same conditions. We understand that upwards of 100 places on the coasts receive telegraphic weather intelligence from the Meteorological Office, and hoist the drum signal to indicate the presence of a storm on some part of the United Kingdom, which there is some probability may be felt at the signal station.

It was not to be expected that the collection of scientific meteorological data, by means of the telegraph, could have rendered from the first complete, satisfactory, and reliable practical results. Nevertheless, it is not too much to say that, in the hands of Admiral Fitzroy, no violent storm visited these islands which had not been preceded by the appearance of his warning signals around the coast. The present intimations of approaching atmospheric disturbances are timeous and generally correct, and where timeous and generally correct, and where they are disregarded the consequences are sometimes disastrous. It is, notwithstanding, desirable that an endeavour should be made to deduce from the frequent recurrence of the same phenomena, general laws for the general guidance. This is the true scientific process, in which the Royal Society is engaged at the present time working out. If meteorology is to be of every-day use, weather-wisdom, that

can penetrate into futurity, must be achieved, and though the goal is difficult of attainment all our observations ought to tend to this much-desired end. Something far different is wanted than an accumulation of statical facts and long tabulations. Mathematical knowledge and exactness of instrumental observations are valuable in compiling averages for climatological research; but the practical meteorologist must confine his attention to the facts and figures for the day. This much, at least, is certain, that but for the service of electricity, meteorology would still be unable to give us the benefit of storm warrings, or even our present very limited ability to forecast weather, which is not the least striking illustration of the dependence of the sciences upon each other.

### NOTICES OF BOOKS.

MIE name of Mr. C. P. Sandberg lately THE name of Mr. C. P. Sandberg latery came before the engineering profession in connection with a practical paper on rails and railway materials. That gentleman appears again in the arena of scientific literature as a translator of a valuable treatise on the elasticity, extensibility, and tensile strength of iron and steel.\* The work was written by M. Knut Styffe, director of the Royal Technological Institute of Stockholm, and it of course originally appeared in Swedish. Its translation into our language has been confided to Mr. Sandberg, inspector of railway plant to the Swedish Government. Mr. Sandberg is himself a Swede, and was educated as a metallurgist in Sweden. He has resided many years in England, and has had great experience in all that relates to the manufacture of iron and steel, especially in that of rails and railway materials. In every respect, therefore, Mr. Sandberg was well calculated for the work of translating M. Styffe's treatise, and he has well performed his task. He has further added a useful appendix, in which he describes some experiments on iron exposed to sudden shocks at different temperatures. The results are remarkable, as showing that iron and steel are, if anything, stronger when exposed to severe cold than at ordinary temperatures. The treatise itself has special reference to the tensile strength of iron and steel, including cast iron. There are many problems connected with this question which are yet but imperfectly solved. Amongst those are the relation between tensile strength and composition, previous mechanical treatment and temperature, &c. It is true, that information on these points is to be found scattered through various books and scientific journals. But M. Styffe has devoted years of patient labour in their solution, and the volume before us contains the results of his systematic and invaluable investigations. The work is accompanied by numerous working drawings and tables, which merit careful study. One table is particularly interesting: it shows the relative value of iron and steel side by side. To all who are studying the side by side. To all who are studying the important subject of the properties of iron and steel, as regards their application to useful purposes, we commend Mr. Sandberg's valuable translation of M. Styffe's treatise.

The "Annual of Scientific Discovery" is

The "Annual of Scientific Discovery" is a work which recently reached us from across the Atlantic. It exhibits the most important discoveries and improvements in mechanics, useful arts, natural philosophy, chemistry, &c., &c. It also contains some well-written notes by the Editor, on the progress of science during the year 1868, a list of scientific publications, obituaries of eminent scientific men, &c. Facing the title page is

a fine portrait of Dr. James D. Dana, professor of natural history and geology in Yale Professor Dana is one of the most distinguished mineralogists living, and is equally eminent as a geologist and zoologist. Our readers will perceive that the volume under notice is similar in character to two which are published annually in England. The information is drawn from similar sources—scientific papers and journals. The work is well edited, and the introductory notes give it an additional interest. The sources of information are for the most part acknowledged in the usual way, although there are some instances where this is omitted. Probably, the editor had forgotten to mark on his cuttings the journal from which he clipped them, and will doubtless be more careful in preparing for his next volume.

Mr. John Brook, of Sheffield, has compiled a very useful little book of French measures and English equivalents (J. Robertshaw, Angel-street, Sheffield), which will be found invaluable to merchants, manufacturers, draughtsmen, and working engineers. Mr. Brook has made every calculation separately, and they are very correct, the fractional parts being exceedingly close. The book is arranged most conveniently for ready reference; it can be carried in the waistcoat pocket, and should be in the possession of everyone having anything to do with French measurements.

The Aeronautical Society of Great Britain have just published their third annual report (Hamilton, Paternoster-row). It contains reports of the papers read, and of the discussions thereon, at the various meetings of the Society during the year 1868. It also embodies a report of the Society's first exhibition, which was held last year at the Crystal Palace. Notices of all these matters have appeared in our columns as they occurred, so that it is only necessary here to refer to the little volume as a correct report of the proceedings of the Aeronautical Society, of which every aeronaut—theoretical or practical—should possess a copy.

NOTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-PLICATIONS.

TO RENOVATE OLD FILES AND RASPS - THE CHEMISTRY OF THE BLAST FURNACE.

SOME three or four years ago we noticed a method of dressing and renovating old files. We mention the process again, having recently seen a French patent for the same thing. A file or rasp worn smooth is immersed for a time in a mixture of one part nitric acid, three parts oil of vitriol, and seven parts water. The time it must be allowed to remain in this acid bath depends upon the quality of the metal. A very hard steel will require a longer immersion than a soft finegrained metal. Anyone would imagine that the acid, acting equally on all parts, would simply dissolve away some of the metal, and leave the file as smooth and useless as before. But such, we are assured, is not the case. Files may be renovated over and over again, and are always as good as new. Some of our readers may perhaps like to try an experiment, so we describe the treatment to be adopted after immersion in the acid. The tool is first well rinsed in water, and then (to ensure the perfect removal of the acid) in milk of lime. It is afterwards to be dried, and the lime is brushed away. When new files are made by this plan, they require a little additional treatment to protect them while in stock. After they have leen carefully dried, and the lime has been brushed away, they are to be brushed over with a mixture of olive oil and turpentine, and, lastly, well rubbed with very fine charcoal powder.

The chemistry of the blast furnace was very ably treated of by Mr. L. Bell in a lecture to the Chemical Society. The lecturer had made it a subject of special study, and has arrived at some novel conclusions. Readers acquainted with the

<sup>\*</sup> Parliamentary Paper, 218, Session, 1868.

<sup>• &</sup>quot;The Elasticity, Extensibility, and Tensile Strength of Iron and Steel." By KNUT STYFFE. Translated from the Swedish by CHRISTER P. SANDBERG, with a Preface by JOHN PRECT, M.D., F.R.S. London: JOHN MURRAY, Albemarle-street, 1869.

marie-arreet, 1869.

† "Annual of Scientific Discovery or Year Book of Facts in Science and Art for 1869." Edited by Samuel Knes-Land, A.M., M.D. Boston: Gould and Lincoln. London: Trubner and Co. 1869.

matter will remember that Scheerer, Tunner, and Ebelman, who have made experiments on the subject, have laid down with apparent precision the parts of the furnace, and the temperatures at which the different stages of the manufacture of iron—the reduction of the oxide and the union of the iron with carbon—take place. The former commonly supposed to happen at a very considerable temperature, while the latter is commonly believed to take place in the hottest part of the Mr. Bell has arrived at conclusions altofurnace. gether different. His results go to prove that the deoxidation of the ore takes place at a compara-tively low temperature, and that the carburization is effected long before the metal is liquefied and separated from the slag. We shall return to this separated from the slag. We shall return to this part of the subject when Mr. Bell's lecture is published, and now only remark that, as regards the carburization, the experimental results detailed seemed to justify the conclusion that it does really happen in an early stage of the process. The relative economy of the hot and cold blast was discussed at some length, and the question—what is the reason that 2cwt. of coal expended in heating the blast will do the work of Sowt. consumed in the furnace—was disposed of, we think, satisfac-torily; but Mr. Bell is inclined to the belief that, by altering to some extent the construction of the furnace, the cold blast may be made almost as economical as the hot. As regards the quality of the metal produced by the two processes, we seem to have ample assurance that as good metal may be made with the hot as with the cold blast, for, as Sir W. Fairbairn remarks, the uncertain character of hot blast metal appears to be due rather to care-lessness and want of attention in the manufacture than to the use of heated air and defects in the process.

# PARLIAMENTARY NOTES.

MR. LEONARD EDMUNDS, it appears, has succeeded in drawing the attention of the House of Commons to his ase. On Monday evening, Mr. Bentinck asked the Secretary to the Treasury whether a copy of a paper entitled "The History of the Edmunds Scandal, by Leonard Edmunds, was now on record in the Treasury; and, if so, whether he would lay the same upon the table of the House.

Mr. Ayrton said Mr. Edmunds had written a letter to the Lords of the Treasury, enclosing a copy of "The History of the Edmunds Scandal, by Leonard Edmunds," and requesting that it should be placed on record in the Treasury. The Treasury was not exactly a place of record, however, for any one who desired to print about himself, and if Mr. Edmunds wished to have his paper presented to Parliament, he had better find some other channel for it.

Mr. Bentinck then gave notice that on an early day after the Whitsuntide recess, he should call attention to the case of Mr. Edmunds, and make a motion on the subject.

On the same evening, Mr. Candlish asked the President of the Board of Trade whether it was true, as had been stated by the Nantes and Havre Chambers of Commerce, in a recent memorial to the French Government, that in the trade between London and the French ports, the Customs authori-ties in London demanded receipts for pilotage from French vessels, previous to granting clearances, which demand was not made in the case of British vessels engaged in the same trade; and, if so, on what ground such demand was made, and on what grounds the vessels of the two countries were subjected to different treatment.

Mr. Bright said it was true that under the Merchant Shipping Act, foreign ships were obliged to pay customs in London, while British ships were not obliged to pay in the same manner. They were both, however, subject to the same rates of pilotage, and were under the same obligation in regard to the employment of pilots. There was some difficulty in knowing what was the origin of the difference, but it was assumed to be that the owners of foreign ships were often not here, and, therefore, not easily accessible in case the pilotage was not paid; and, also, that it was a better plan for the ewners of foreign ships, as it secured them from the supposed chances of imposition. However, the point would be reconsidered in the amendments to the Merchant Shipping Act, and in all probability the distinction would be removed.

# OUTFALL OF THE HUMBER. BY MR. W. SHELFORD.

T the meeting of the Institution of Civil En-A gineers, April 27, 1869, Mr. C. H. Gregory, President, in the chair, the paper read was on the outfall of the Humber, by Mr. W. Shelford,

The estuary was described as the outlet for the fresh waters from a drainage area of 10,500 square miles, or one-fifth of the whole area of England; but the present paper only treated of the outfall, the observations being arranged under four heads.

1. The facts in connection with the past and present condition of the outfall and of its peculiar feature—Spurn Point. Under this head the disfeature—Spurn Point. Under this nead the dis-trict was said to consist geologically of diluvial clay resting upon chalk, of which the surface was proved to be below the bed of the river at its outfall. The extent of the marshes and the fens adjoining the estuary and their levels were then given, and it was shown that the area of the reclaimed land below high-water spring tides at sea was 290 square miles, while the present area of the estuary at high-water was only 110 square miles. It was also shown that the marsh banks were generally repaired in the thirteenth century. The waste of the Holderness coast, from Bridlington southwards, was stated to average 24 yards per annum, and it was inferred that 1,000 years ago the coast line must have been at least 2,250 yards It was thought possible, that the further east. promontory might then have had a short point, with an ebb channel and a good roadstead close to it, and that here the Danes landed in A.D. 867. Here also gradually rose the town of Ravenser, which was one of the most flourishing ports of the kingdom in the fourteenth century. In 1250, an outlying hamlet of this town, called Ravenser Odd, originated. It was upwards of a mile distant from the mainland, and the access to it was from Ravenser by a sandy road scarcely elevated above the sea. In 1289, the Grimsby people claimed certain privileges there, calling it an island, and probably basing their claims upon its previous insular character. In 1360 Ravenser Odd was totally annihilated by the floods of the Humber and inundations of the great sea. The last mention of Ravenser itself was in 1552.

In 1622, it had been said that "parcel of the Spurnhead, which before did adhere to the continent, was torn therefrom by the sea, and is now in the nature of an island." In 1676, Angell's lights were authorized, in consequence of a broad long sand which had been thrown up at the mouth of the Humber six or seven months before. Smeaton thought that this sand had afterwards become connected with the mainland, and so formed

the Spurn Point of his day.

The author proceeded to state that Sunk Island was spoken of as a novelty in 1667, and was deed as an accumulation of sand and mud, also that Frismersh, or Fresh Marsh, formerly occupied its site, and was destroyed soon after 1362. The leading features of the outfall were then pointed out, as shown by the following charts, of which cartoons were exhibited, viz., Greenville Collin's Chart of 1634, Robert Mitchell's of 1778, Hewett's of 1828, and Calver's of 1852. According to Smeaton, "Spurn Point was a necessary appendage to the cliffs of Holderness, and was in a continual state of travel southward and westward : the southward movement being accompanied by a corresponding encroachment of the river on the Lincoln Coast, and the westward movement by the abrasion of the coast of Holderness by the sea. appeared from these charts that seaward of Spurn a large accumulation of shingle had taken place, and that on the Humber side extensive accretions, including Sunk Island, had formed. Also, that the main flood stream set in to the south of the Bull sand, and the ebb stream set out to the north

The southward movement of Spurn was shown to have varied, and to have been as follows :-

1676 to 1766 . . . 20 yards per annum 1766 , 1771 . . . 56 , , , , 1771 , 1786 . . 10 , , , 1786 , 1851 . . . 4 6 , , , 1851 , 1864 . . 8 7 , , ,

The westward movement was shown by the history of the lighthouses to have averaged 3 yards per annum since 1771. It was also stated that since 1863 an attempt had been made to arrest this movement, and the danger of so doing was pointed out.

2. The ascertained alterations in the tidal regime. Under this head evidence was offered to prove, flower; and numerous that the tidal range of the Humber at Hull mrde in various classes.

increased 3ft. between 1852 and 1828, and 2ft. between 1828 and 1725, making 5ft. since 1725: and if the increase had been continuous since the rise of 4ft., recorded to have taken place about 1357, it would make a total increase of 9ft. in about 600 years. Evidence was also offered, which was considered sufficient to justify the general conclusion, that the tidal capacity of the Humber below low water had increased between 1828 and 1852.

3. The relative value of tidal and fresh water at the outfall. After demonstrating that the discharge of a great flood from the drainage area would only equal a fourth of the tidal capacity, the author expressed the opinion, that whilst there was a wide field open to any one who would undertake the investigation of the phenomena connected with the discharge of so large a volume of fresh water as that which pulsated through the Humber to the sea, yet at the outfall there were other forces at work, of sufficient magnitude to throw into shade the effect produced by occasional freshes acting

directly upon it.

4. The relation of the operations of Nature and of engineering works to the facts recorded. Broadly stating that the tidal action of the estuary had improved, notwithstanding the encroachments upon its tidal area, the author endeavoured to deduce the cause. He considered that in 867 the area at high water must have been much greater and the depth less than at present, that the south flood tide and the north ebb tide would together produce a sand like the Bull sand, which would accumulate till it became an island, but as the flood channel opened, the ebb channel would become weaker, and would be eventually closed by the shingle from the cliffs of Holderness, and that Spurnhead was in this state in 1250, when Ravenser Oud originated. He believed that the consequent contraction of the entrance, combined with the accretions in the Humber and the repairs of the marsh banks, increased the velocity, raised the high water line of the estuary, and depressed the high water level, and that both Ravenser Odd and Freshmarsh were destroyed by the improved tidal action. The destruction of Ravenser itself was attributed to the advance of the sea upon the Holderness coast, and was supposed to have been accompanied by the outflanking of Spurn Point, which had been destroyed by this means. It was pointed out that the Spurnhead was again an island in 1622, and in turn again became a promontory, as the flood channel travelled southwards, and the ebb channel became closed. said that the old action was being repeated at the present time; the Bull sand was the island, but the estuary was now so narrow, and the forces at work in it so great, that it could not rise to the level of low water. It was also said that the sea continued to encroach on Holderness, and would in the present state of things again outflank the Spurn neck.

In conclusion, the author stated that the low water channels up to Hull were now comparatively straight and confined, and the action of the ebo tide was therefore better than ever; but that the channels abreast of Spurn were travelling southwards, and the shingle was still endeavouring to

close the estuary.

# THE ROYAL HORTICULTURAL SOCIETY.

AST Saturday the above society held a show of pot roses and spring flowers at South Kensington, when some choice varieties of roses were exhibited. There were also shown some fine specimens of cut tulips, auriculas, rhododendrons, polyanthuses, lilies of the valley, pansies, Alpine polyanthuses, lines of the validy, pausion, ..., plants, &c., the whole forming an excellent, varied, and highly successful collection. The principal prizes were awarded as follows:—viz., Class 1, and highly successful collection. The principal prizes were awarded as follows:—viz., Class 1, nurserymen, for nine distinct roses: first prize, Mr. W. Paul; second, Mr. C. Turner; third, Messrs. Paul and Son. Class 2, a second prize awarded to Mr. J. James (amateur), for six roses. Class 3, for twelve new roses: first prize to Mr. C. Turner; second prize, Mr. W. Paul. Extra prizes were also awarded to the whole of the above-named exhibitors. Mr. T. S. Ware and Messrs. J. Salter and Sons carried off the first and second prizes for collections of Alpine plants. Messrs. Reeves Brothers were successful in gaining first honours for the lilies of the valley. Messrs. Salter and Sons obtained the second prize under the same head. Messrs. J. Standish and Co. were awarded the first prize from amongst several competitors for their miscellaneous collection of plants in flower; and numerous other minor awards were

# AUXILIARY PROPELLER FOR SAILING SHIPS.

BY MR. JOHN BOURNE, C.E. 

# BOURNE'S AUXILIARY PROPELLER.

A FORTNIGHT since, we described in general terms Mr. Bourne's auxiliary propeller for aiding sailing vessels when overtaken by a calm. This apparatus, it will be remembered, was temporarily fitted on board the "Warwick Castle," on which vessel its efficiency was demonstrated in which vessel its emeterory was demonstrated in dock. Since the experiment recorded by us, a trial has been made in the river, when the ship was leaving for Calcutta. The propeller stemmed the tide for a short time until the wind became too strong, which of course was an exactly oppo-site condition to that under which the services of the apparatus would be required. Hence, no exact results were arrived at, although, what was done was satisfactory, and tallied with our expec-

tations. The apparatus has been removed from the "Warwick Castle"—where it was only rigged up for the purposes of a trial—and, we believe, is to be fitted permanently on another of the "Castle"

to be fitted permanently on another of the "Castle line of ships.

We now give our readers detail particulars, and an engraving of this useful piece of mechanism, from drawings which were kindly placed at our disposal by Mr. Bourne. Our engraving represents a cross section of a vessel fitted with the apparatus. The engine actuates a pinion shaft gearing with a large spur wheel carried by a shaft, with two cranks in it, from which cranks the connecting rods B B proceed to the side of the ship to ing rods BB proceed to the side of the ship to give motion to the oar H, which is carried by the swivelling crane G, which when not in use may be shut up against the sides of the vessel. One of the the centre of which the shank of the car pass

connecting rods which derives its motion from one of the cranks works the car to and from the side of the ship, while the other connecting rod which derives its motion from the other crank works a short handle or tiller connected with the oar. The throw of the two cranks is the same; but one being set a certain distance in advance of the other, it follows that when both are in action a sculling motion is imparted to the oar, one of the cranks impelling the oar and the other feathering it.

The position of the cranks relatively with one another is shown at C. One of the connecting rods is connected to the top of the car at D, and the other to the short feathering arm or tiller E. F is the hinge joint on which the oar reciprocates, and through a short tube or cylindrical socket, in

being supported upon the edge of the socket by a collar formed on the oar to the end that the oar may be feathered by being partly rotated by the feathering arm during the time in which it is reciprocated. The hinge is carried by the crane G. With this useful apparatus fitted on board of ships in the China trade, we shall have an additional and important interest imparted to the annual tea

ON THE BRIDGE OVER THE THAMES CARRYING THE WEST LONDON EX-TENSION RAILWAY.\*

By Mr. LAWFORD, M. INST. C.E.

HIS bridge was erected for the purpose of carrying the West London Extension Railway (which connects the North-Western and Great Western Railways with Victoria Station, at Pimlico), across the River Thames, between Chelsea and Battersea, under the provisions of an Act of Parliament, which received the royal assent on August 13, 1859. The bridge consists of five segmental arches of wrought iron, each arch having a span of 144ft. on the skew, with a rise of 16ft., or 1-9th of the span. There are also, on the Middlesex side of the river, six, and on the Surrey side four, land arches of brickwork. each with a span of 40ft. and a rise of 10ft. The total length, therefore, of the whole structure is 1.270ft. The abutments and piers of the five main openings are massive pieces of masonry, and are carried to a depth of 36ft. below Trinity highwater mark, and 14ft. below the bed of the deepest part of the river. The soffit of the arches at the crown is 22ft. above the same point, i.e., Trinity high-water mark, in accordance with the requirements of the Admiralty and the Conservators of the River Thames. The level of the rails is 26ft. above Trinity high-water mark. The width of above Trinity high-water mark. the river between the two abutments is 776ft. on the skew and 706ft. on the square. The width of waterway afforded is 720ft. The angle at which the bridge crosses the river is 75deg. The greatest depth of water is 22ft. below Trinity greatest depth of water is 22ft. below Trinity high-water mark, the average rise and fall of the tides at this place being about 13ft. 6in.

were constructed in coffer dams, the inner row of piles being 5ft. from the outer edge of the lowest course of masonry, and were driven to a depth of 15ft. below the bed of the river; the outer row were 5ft. from the inner row, and were driven to a depth of only 8ft. from the same point, the space between the two rows of piles being filled with puddled clay. At the conclusion of the work the outer row of piles were drawn, but the inner row of piles were cut off level with the bed of the river. As the masonry of the piers proceeded, the space between them and the piles was puddled clay, well trodden in, to a height of 3ft. above the bed of the river. Each pier stands on a bed of concrete 2ft. thick, extending 3ft, beyond the lowest course of footings. On the concrete is laid a course of York landings. 1ft. thick, and projecting 1ft. beyond the footings.

The foundations are carried up in a brickwork to within 2ft. of the bed of the river, where there is a through course of stone 2ft. thick. From this point to the springing of the arch the pier is faced with picked face ashlar of Bramley Fall stone.
There is a second through course of stone half way between the bed of the river and the springing, and the upper, or last 7ft. of the piers, including the springers (which are 3ft. thick), are entirely solid The two abutments are built similarly to the piers, except that they have hollow chambers, filled with gravel to a height of 8ft. above the springing of the arch; each abutment being just on the edge of the river required only half a cofferdam for its construction. All stone work of both piers and abutments above springing height is tool dressed. The concrete used in this bridge was composed of five parts of gravel to one of blue lias lime, and the mortar of two measures of sharp sand to one of the same sort of lime.

Each of the river arches is composed of six wrought-iron ribs, arranged in pairs, 2ft. 6in. apart from centre to centre. The arch or voussoir of the four main or inside girders is formed of in. vertical plates, 39in. deep at the springing and 24in. deep at the crown, with double angle irons, each 4in. by 31in. by 31in., top and bottom, to which the flanges are attached by means of

\* Abstract of paper read before the Civil and Me-nanical Engineera' Society.

There is also a packing strip 8in. by kin. between the angle iron and the flanges. The flanges consist of two sin. plates, 18in. wide. The upper member of the inside ribs is a horizontal parallel girder, similarly constructed, but only only 24in. deep, throughout its entire length. The vertical web is \( \frac{1}{4} \) in. plate from the pier to the point where the upper and lower member inter-sect, i.e., 15ft. from the centre of the arch, and from this point both vertical webs are gin. in thickness. The bottom flange of the horizontal girder consists of one plate 164in. wide by 1in., two angle irons 3½ in. by 3½ in. by ½ in., and a pack-ing strip 8 in. by ½ in. The upper flange is 15 in. ing strip 8in. by in. The upper flange is 15in. wide, all other dimensions being the same as those of the lower flange; but the top plate is slightly curved inwards towards the rails. In the two outside ribs the voussoir is constructed as already described, but is 30in. deep at the crown and 39in. at the springing. It may be as well to mention here that in these two girders, on the outside faces of the arch, all the rivets, excepting those in the angle irons, are countersunk, no cover plate either being visible at the joints. The whole centre web presents, therefore, the appearance of one smooth unbroken plate. This centre web is a \$in. plate, the two flanges are single \$\frac{1}{2}\$in. plates 16in. wide, the angle irons 3\$\frac{1}{2}\$in. by \$\frac{3}{2}\$in. by \$\frac{1}{2}\$in., and the packing pieces 8in. by \$\frac{1}{2}\$in. The upper member is constructed in the same manner as that of the inside rib, but it has throughout the whole span 4in. vertical plates, and is only 18in. deep at the crown of the arch. The upper flange is 18in. wide, and is parallel with the lower flange is 18in.
wide, and is parallel with the lower flange, which
is only 15in. wide. The angle irons and packing pieces are of the same dimensions as those already described for the inside top members. The total depth of the girders, both inside and outside at the centre of the arch, is the same, viz., 48in.

ing, 80 square inches; in the upper member do., 43 square inches—total, 123 square inches; and at the centre of the arch, where the upper and ower members are together, 105 square inches, the mean average being 114 square inches. These are the full sectional areas, including the rivets. The voussoir and the upper horizontal girder of the four main girders are connected together by a lattice spandrel, composed of H-iron, of three different sizes, viz., 7in., 6in., and 5in. by lin. A stiffening bar of flat iron, gin. thick, is added to each side of the H-iron, connecting the lattice bars throughout at the angles of intersection. In the outside girders the lattice and stiffening bars are all made of double T-iron, riveted together, thus I, and of the same dimensions as the H-iron, i.e., 7in. by 31in., 6in. by 3in., and 5in. by 21in., all Jin. iron. Each pair of ribs is connected pear the haunches by means of frames, composed of angle irons, cross braced and riveted to the ribs. forming an open box girder. This principle is continued to the crown of the arch, where the voussoir and top girder unite in a double cell. Each pair of main girders are braced together at the haunches by means of trellis transverse girders 2ft. 6in. deep, carried up at equi-distant intervals to within 10ft, of the centre of the arch There are seven of these in each half arch; they are composed of angle and bar iron, 31in. by 31in. The top members of the main ribs are secured together by the cross girders, which carry the roadway; the arc fixed over the whole length of the bridge, 4ft, apart from centre to centre, and are composed of a middle web of iron, 10in, deep and in. thick, the bottom of which is flanged with double angle iron, 3½in. by 3¼in. by ¼in., and the top with double channel iron, on the lower flange

The sectional area of each of the four main

girders is as follows:-In the arch at the spring-

brackets riveted on to each of the angles. The are three sets of these tie-rods in each half arch. Upon the end of each arch or voussoir a plate of cast iron, 3in. thick, is fixed, the back of which is planed quite true and even. These, again, fit into heavy cast-iron shoes (weighing 2 tons each), let into the stone skewbacks of the piers and abut-ments, and by means of wrought-iron wedges are finally adjusted in their seats. Contraction and expansion are provided for as follows:—Cast-iron standards are bolted to the stonework of the piers and united by a cast-iron frame, secured with bolts

which the buckle plate flooring rests.

cross girders rest on the lower flange of top main

girder, and are secured in their places by iron

knee-pieces, riveted through the centre webs. The

main or bearing girders are again cross braced by diagonal rods, bolted to a centre plate, and to

them in position, at the same time allow for horizontal motion. A bod and bearing plate, planed perfectly parallel, are fixed under the ends of the girders, upon which they slide.

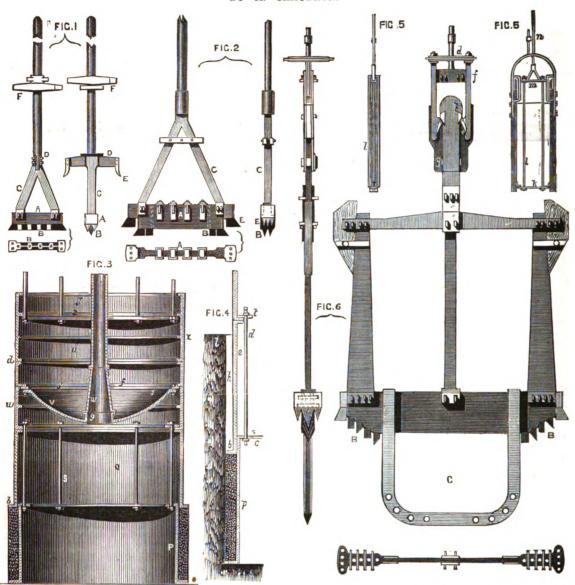

The railway is a double line of mixed gauge, and is carried over the bridge by means of longitudinal timbers with transons every 10ft. ballast is used all over the bridge. A cast-iron moulding is attached to the horizontal girder, throughout its whole length, and a cast-iron plinth is bolted on to the top of the same; an ornamental cast-iron parapet is fixed on the plinth, and the whole is surrounded by a wooden hand rail. The iron of which this bridge is built was manufactured by the Shelton Iron Company, at Stoke-upon-Trent, and is, perhaps, better known as Lord Granville's In the experiments made for testing the quality of the iron, it bore a tensile strain of nearly 18 tons per square inch, without showing any signs of fracture. The H and T-iron used in the signs of fracture. The H and T-iron used in the spandrils was rolled by the Butterley Iron Company. About three-quarters of the ironwork was made and put together by Messrs. Calvert, of York, and, on the collapse of that firm, it was completed by Mr. Charles Lungley, the iron ship-builder of Deptford. The contractor for the work, and, indeed, for the whole of the West London Extension Railway, were Messrs. Brassey and Ogilvie—names well-known in the railway world and a sufficient guarantee that the work would be well and substantially carried out. The width of the bridge between the cast-iron parapets is 30ft. in the clear. The total width of the piers from out to out above springing level is 35ft. 6in., and at that level, including the cut waters, 53ft. 6in. The total cost of the bridge was £104,000, or £82 per lineal foot, and £2 10s. per superficial foot. The materials used in its construction were 2,000 cubic yards of concrete, 11,100 cubic yards of brickwork in mortar, 130,000 cubic yards of brickwork in mortar, 130,000 cubic feet of stone, 2,160 tons of wrought iron, 366 tons of cast iron, 2 tons of lead, and 28,000 cubic feet of timber, exclusive of the piles. This bridge was the joint design of Messrs. Baker and Bertram, the chief engineers of the Great Western and North-Western Railways. It was opened for public traffic on March 2, 1863, since which date some hundreds of trains have passed over it daily, and I am not aware that, up to the present time, any expense whatever (beyond the maintenance of the road) has been incurred, either in repairs or other-The bridge was only 15 months under wise. construction, i.e., from the time the first stone was laid until a locomotive passed over the river. The bridge was very severely tested on January 7, 1863, by Captain Tyler. The narrow gauge load consisted of two locomotives and tenders, funnel to funnel, and two tank engines; total length of train 132ft., total weight 176 tons. The broad gauge 132ft., total weight 176 tons. load consisted of two tank engines, in the same position as the narrow gauge engines, each drawing six loaded coal waggons; total length of train 276ft., total load 292 tons; these two loads, collectively, being equal to about 21 tons per lineal foot. First, the narrow gauge load passed over No. 1 arch at speed, the deflection 5-100ths of a foot. Second, the broad gauge load passed at speed—same result. Third, the broad gauge load on one road and narrow gauge on the other, both passed together over No. 2 arch at speed. On going over No. 1 arch, No. 2 rose 3-100ths of a foot. On going over No. 2 it deflected nearly 10-100ths of a foot, rise and fall 13-100ths of a foot. Fourth, both loads were brought to rest on No. 2 arch, deflection 11-100ths of a foot. When the loads passed slowly over No. 3 arch, No. 2 rose 2-100ths of a foot, rise and fall 13-100ths of a foot. Both loads remained stationary for some time on this arch, but no further deflection took place, and, with the removal of the load, the girders rose simultaneously to their original height. Fifth, the same thing was done on No. 3 arch with a precisely similar result. Sixth, the same experiment was made on the fourth arch, and in exactly the same manner as the fourth experiment-rise of arch 2-100ths of a foot, deflection 10-100ths of a foot, rise and fall 12-100ths of a foot. Seventh, the same thing was done on the fifth arch; the rise was 2-100ths of a foot, deflection 8-100ths of a foot, rise and fall 10-100ths of a foot. The bridge was very steady throughout these experiments, and there was very little lateral vibration, even when both loads passed at the same time in the same direction, either slowly or at speed.

A MEETING of Liebig's Extract of Meat Company and nuts. These standards have recesses to re-was held on Wednesday, and a dividend declared of ceive the ends of the horizontal girders, and secure 6 per cent , together with a bonus of 5a. 6d. per share.

# SHAFT-SINKING MACHINERY.

BY M. CHAUDRON.

## CHAUDRON'S SHAFT-SINKING APPARATUS.

THE present method of sinking shafts and tubbing is, when great volumes of water have to be contended with, exceedingly expensive and dangerous for the life of the workmen. arises from the great expense for machinery and fuel necessary for pumping, and from the fact of the workmen having to do their work more or less whilst standing in the water. The danger is proved by serious accidents, arising from the giving way of the tubbing, and from breakages in the pumping machinery, which is suspended above the workmen. Many attempts to sink shafts have had to be abandoned, after enormous sums had been spent in fruitless exertions to master the water. These circumstances induced M. Chaudron, an engineer of mines in Belgium, to bring out his patent system of boring or sinking shafts through aqueous strata, the principal features of which are:—1. An iron tubbing, made by preference of cast-iron rings (cast in one piece), lowered from the surface gradually, and superimposed one above the other as the work proceeds, a complete watertight joint between these rings being obtained by the interposition of a thin layer of lead. 2. The Boite a mousse, or stuffing box, for securing an infallibly watertight junction with the underlying stratum.

By this system the necessity of pumping the water out of such pits or shafts during the progress of the work, is by this system obviated, the apparatus employed being so arranged as to effect the complete isolation of the water-bearing strata, thus enabling the work to be carried on through any depth, at a much less cost, and in a much shorter time, and also with less arduous labour than has

been possible with the means previously employed. By the old process of sinking shafts the workmen had to work in water down in the pit, in a dangerous position, with the pumping machinery sus-pended above them; by the improved system this is entirely obviated, as nearly the whole operation

is performed from the surface of the ground.

For this purpose a boring is first made through the strata, which is effected by means of one or more boring tools, having a number of teeth or chisels which act upon the Chinese system. The tool, after being lifted up by suitable apparatus for a height of about Ift. or 2ft., falling down and crushing the rock. These tools are of a width corresponding with the diameter of the boring to be made, and when the boring is of a large meter, a small central boring is first made with a small tool having a number of chisels all along its under surface, and sometimes also one or more other chisels on the ends of the crossbar fixed higher up on the rod of the tool, which serve to smooth off the side surface of the boring made by the lower chisels. After this, the boring is enlarged by means of one or more larger and heavier tools in succession, having a number of chisels at each end, and a projection in the middle, which passes into the central boring previously formed by the smaller tool, and which serves as a guide. Crossbars acting as guides are also fixed upon the rods of the tools. The boring with the tools of the smaller diameter is, however, always kept so much

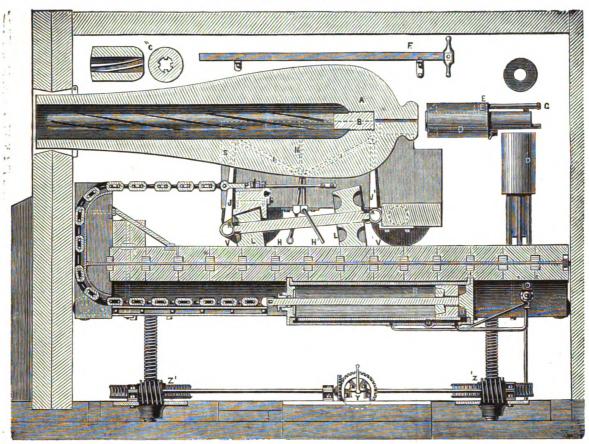

tacle, into which the debris fall, and which is withdrawn when full. Or as the work proceeds, the clearing of the debris may be effected as usual by means of an open metal cylinder, closed at bottom by valves opening inwards, so that by working such cylinder up and down at the bottom of the boring, the debris are made to enter the same, and

are then raised to the surface.

In our engraving, figs. 1, 2, and 6 show various forms of these boring tools. Fig. 1 is a front elevation, a side elevation, and a plan of the under side of the smallest description of tool for making the preliminary boring in semi-hard strata. The bar A, carrying the cutting chisels B, is fixed by keys to the forked end of the rod C, and at a point higher up on the rod is fixed an arm D, at right angles to the bar A, carrying at its ends two other chisels E for smoothing the sides of the boring; F F are guides for keeping the tool in a central position. After the preliminary boring has been made with these tools, it is widened by the use of fig. 2. This tool has chisels B only at the ends, and, in order to keep it central with the preliminary boring, it is provided with a guide G. The preliminary boring is first enlarged by the The preliminary boring is first enlarged by the chisels B, and a further enlargement is effected by the chisels E, situated higher up. Fig. 6 shows a front elevation, side elevation, and and plan of a boring tool, in which the teeth or chisels B are arranged on an incline for the purposes before set forth; the guide, or loop G, being made to fit loosely into the smaller boring made by the preseding test. It this boring smaller diameter is, however, always kept so much in advance of the larger boring, that the debris from the latter shall always fall into the former, and for this purpose the teeth of the enlarging tools are, by preference, arranged on an incline, so as to produce a boring, being connected to the smaller boring by an inverted cone. In the smaller boring may be suspended a metal reception in the purposes before set forth; the guide, or loop G, being made to fit loosely into the smaller boring made by the preceding tool. In this boring suspended a bucket, provided with two or more pawls, which, in catching against the side of the boring, hold the bucket suspended therein so as to receive the debris made by the boring tools. The recovery of broken rods and tools is easily

# THE RODMAN GUN IMPROVED.

BY MR. C. PEMBERTON, R.N.

effected in a way well understood, and presents no novelty.

When the boring through the aqueous strata has been completed, the water from these is effectually cut off from the boring by the following apparatus and mode of operation:—A strong cast-iron cylinder, shown in half sectional elevation at P, fig. 4, is constructed of a somewhat smaller diameter than the boring, having at the bottom an external flange, a, the extreme diameter of which corresponds as nearly as practicable with the diameter of the boring; the upper end of this cylinder fits like a gland into the lower end of a second strong cast-iron cylinder, Q, which has also an external flange, b, equal in diameter to that of the well. The space formed on the external surface of the bottom cylinder, between its lower flange and the flange of the upper cylinder, is filled in with moss or other similar suitable substance, R, which is to act as a packing between the lower cylinder and the side of the well. The lower cylinder, P, is suspended from the upper one, Q, by means of suspension bolts, S, passing through an inner flange, C, formed on the upper end of the former, and through a ring, T, resting upon the flanges, d, formed on the upper cylinders, in such manner, that when the lower cylinder is in place at the bottom of the boring, the upper one is free to slide down upon it, and thus compresses the moss packing, as shown at fig. 4. To the upper cylinder, Q, is now fixed a third cylinder, U, fig. 3, by means of bolts passing through the internal flanges, d, a watertight joint being insured by means of lead packing between the meeting surfaces. To a flange, f, on the interior surface of this third cylinder, is bolted a strong diaphragm, V, of an inverted dished form, so as to withstand considerable pressure from below. In order to facilitate the subsequent removal of this diaphragm, it is made of a somewhat smaller diameter than the cylinders, and bolted to them through a ring, Y. In the centre of this diaphragm is formed an opening g, to which is fixed.

Upon the cylinder U, is now fixed a further one X, also in a watertight manner, and the four thus combined are then lowered by suspension rods Y, fixed in a ring Z, into the boring, until, by the aid of the diaphragm, they float in the water contained therein. Other cylinders are now fixed in succession, in a like watertight manner, to those in the boring, which are, consequently, made to sink

gradually down from the supperadded weight, which sinking is regulated by the suspension rods or chains worked from above, and also by letting in a certain quantity of water above the diaphragm V through the central tube W. This tube also serves to allow clearing implements to be passed down the boring, below the diaphragm, in order to clear out the debris before the cylindrical lining arrives at the bottom. When this has been accomplished, that is to say, when the bottom cylinder has arrived on the seat formed for it, in the impermeable strata below the aqueous strata, the bottom cylinder is pressed by the superincumbent weight down over the gland cylinder P, thus very forcibly compressing the moss packing R, as before described. A watertight packing is thus formed round the lower end of the cylindrical lining, which prevents the water of the upper strata from penetrating into the interior of the lining from below. An annular space h exists between the outer surface of the cylindrical lining and the surface i of the boring, which space is now, by preference, filled in with concrete, as although the moss packing at bottom, and the watertight joints of the lining, prevent the penetration of the water to the interior, yet it is well to guard, by this means, effectually against any leakage that may take place in the lapse of time.

This filling in with concrete may be effected by means of narrow boxes, constructed as shown in sectional front and side elevation at fig. 5, the bottom, K, of which is connected by rods l, to a cover or piston m, attached to a long rod n, worked from above; these boxes are filled with concrete, and are lowered in the annular space, at the bottom k, and piston m. When the cylindrical lining has been made perfectly watertight, and all communication with the aqueous strata cut off, the water is emptied out of the cylinders and the diaphragm removed A strong segmental-ribbed cast-iron curb or sill is then by preference firmly fixed in the boring below the lower end of the gland cylinder P, to connect the two firmly together, so as to provide a firm foundation to the lining. After a perfectly watertight lining has been made to the boring, through the upper strata in the above described manner, the sinking of the shaft or pit may be continued in any desired way, until the strata bearing the mineral or substance to be gained is reached.

sion, in a like watertight manner, to those in the boring, which are, consequently, made to sink ing shafts through aqueous upper strata are—the

complete isolation of such aqueous strata, the great strength of the cast-iron lining, and the possibility of making the joints thereof perfectly watertight; great economy in the expense and duration of the work, considerably less arduous labour for the workmen, and the possibility of passing through all aqueous strata, no matter what their nature and thickness may be. The invention has been well tested, and with great success, at the mines of the "Société de l'Escarpelle," near Donai, Department du Nord, and at the Mines de l'Hopital, in the Department of Moselle, France. It has also been applied with equal success in Prussia and Belgium. This system obtained a Grand Prix Gold Medal at the last Paris Exhibition. We may add that Mr. Henry Simon, of No. 7, St. Peter's-square, Manchester, is the British agent for this invention.

# THE RODMAN GUN IMPROVED.

OUR readers are familiar with the 15-inch Rodman smooth-bore gun at Shoeburyness, which we recently illustrated. In the annexed engraving they will see it as adapted for carrrying rifled projectiles, by Mr. C. Pemberton, of the Royal Navy, whose method of conversion we are about to describe by the aid of our engraving. A shows the gun in section, whilst B is a rifled bar, screwed firmly into the end of the bore of the gun, and grooved to receive a number of spirally-formed ribs, which are cast in the shot to the requisite twist, as shown at C. This method of rifling is, of course, not confined to the Rodman system of guns; it may be applied to other descriptions of artillery, or new guns may be constructed on the principle. This plan of rifling shot is to obviate the destructive method of cutting up the bore of the gun, which nicking process has been proved to reduce the life of large guns 20 per cent. to 50 per cent. It is also clear that this shot of chilled iron is from the greater amount of surface chilled, more homogeneous, harder, and cheaper than the present studded shot, from its being a plain casting.

In loading this gun, a canister, shown at D and D  $^1$ , is employed, into which is fitted an air-tight piston E; on to this is pushed a properly made elastic wad. The canister is then filled with the requisite quantity of powder, on the top of which is placed a cake of powder, previously prepared in

a mould, so as to fit the end of the chamber of the gun. The canister, with its contents, is then put into the muzzle of the gun, and a flexible tube screwed on at G; it is then pushed to the bottom of the gun with the rammer F; air is then forced by an air pump through the tube G, which, acting against the piston E. will force back the canister. leaving behind the whole of the powder with the wad in front ready to receive the shot. By this method of loading, worming and sponging will be unnecessary, flannel bags not being used with the powder, thus economizing time and ensuring safety.

Mr. Pemberton proposes to work the training gear by the old method of side tackle hooked on the eye of catgut rope H H 1, which, when pulled to the right or left by steam or manual power, draws down the rods II 1, and with them the levers JJ 1 and K K, which force down the rollers L L on to the platform, thus taking the weight from the trucks V V 1, and causing the gun to roll in the direction required, to an angle of 40dog. of training right or left. After firing, the gun can be rolled round in its own length 90deg. for the purpose of reloading, with the port closed, by pushing in the pin S, so as to prevent the full action of the foremost lever J and front roller L from touching the platform; the side tackle at H being then pulled, the weight of the gun will rest on the after roller L 1, and two foremost trucks V, and will turn round. After the gun is loaded and again pointed to the porthole, then by pulling on the rope N until the rold J J are above the horizontal line the miles T I are the life of the porthole. zontal line, the rollers LL are thus lifted from the platform, and there they will remain without being secured until again pulled down by either of the side tackles H H, the pin S having been drawn back.

The recoil of the gun is checked by the cylinder R and piston O, connected to the gun carriage at P and piston rod. Air alone, or air and fluid, can be used in the cylinder, and the escape regulated by the cock M, through which the air and fluid is forced during recoil. This apparatus is also used to pull the muzzle of the gun into the porthole, in conjunction with a steam or hydraulic engine, which pumps the fluid and air from one end of the cylinder R and forces it into the other end, thus causing the piston to move in the cylinder, and in so doing draws out the gun to its proper position for training. When the gun requires to be elevated or depressed, the process of muzzle-pivoting can (without interfering with the gunners) be carried on by the men below the platform, or by steam power applied to the intermediate shaft at Y, which would turn four elevating wheels ZZ! thereby raise or lower the gun, platform, and recoil cylinder. The advantages of the muzzle-pivoting gear are, that the operation can be carried on vithout interfering or delaying the time required for loading the gun, the turret or shore buttery will not require to be so high by the distance of method of elevating the muzzle of gun leg. or about 2ft.). There is a saving of (say 18deg. or about 2st.). There is a saving of weight and expense, and the enemy's target is reduced in height.

This system, on a small scale, was fired first in 1865, to test the system of rifling and the recoil cylinder, both of which answered satisfactorily. The length of bore of the gun used was 20in.; diameter of bore, 1.83in.; area of bore reduced by rifled bar, 1.5th in.; spiral uniform, one turn in the length of the bore; weight of shot, 9oz.; length of shot, 11 diameter, foremost end slightly convex, after end rounded, as shown in the engraving; charge of powder, 1 toz; range, 40 yards. tration, two plates of wrought iron fixed 4in. apart, the first §in. thick and the other §in. A much quicker spiral can be attained on this system than with the ordinary method of rifling, the angle of spiral being reduced more than one-half, and the ody of the gun is in no way affected by this mode of rifling.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending May 8, was 2,758. Total number since the opening of the Museum, free daily (May 12, 1858). 1,560,886.

THE number of visitors to the South Kensington THE number of visitors to the South Kensington Museum during the week ending May 8, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 9,644; Meyrick and other galleries, 1,574; on Wednesday, Thursday, and Friday (admission 6d.) from 10 a.m. till 6 p.m., 2,201; Meyrick and other galleries, 155; total, 18,674. Average of corresponding week in former years, 12,052. Total from opening of Museum, 8,407,479. INSTITUTION OF CIVIL ENGINEERS.

T the last meeting of the Institution of Civil A Engineers, held May 11, 1869, Mr. C. H. Gregory, President, in the chair, the president stated that during the past week he had visited Paris, accompanied by Messrs. Bidder, McClean, Cubitt, Hemans, and Manby, to present to the Emperor of the French the diploma of honorary member of the Institution of Civil Engineers. His Majesty received the deputation most graciously, and requested that his sincere thanks might be conveyed to the members of the Institution for the honour conferred upon him, and expressed his gratifica-tion at being elected a member of such a body. The cordiality which marked the official reception, and the special and even friendly hospitality which followed it, showed that their illustrious honorary member warmly appreciated the compliment which has been paid to his scientific attainments, and to his enlightened encouragement of public works, and that he desired, through the deputation, as representatives of the Institution, to do honour to the engineers of this country.

At the closing ballot for the session, eleven candidates were balloted for as Associates, and declared to be duly elected, viz.:—Mr. John Henry Abbey, borough surveyor, Huddersfield; Mr. Edward Brotherton Carroll, locomotive superintendent, Bombay, Baroda, and Central India Railway; Mr. James Farrar, engineer to the Bury way; Mr. James Farrar, engineer to the Bury (Lancashire) Improvement Commissioners, &c.; Mr. Frank Garrett, Leiston; Mr. Henry Newson Garrett, Leiston; Mr. James Howard, M.P., Bedford; Mr. Harry Edward Jones, engineer of the Wandsworth Gas Works; Mr. Thomas Miller, Ipswich; Mr. Frederick Peck, Furnival's Inn; Mr. Henry Minchin Simons, Bowling Iron Company; and Mr. James Williams, secretary of the Midland Railway Company.

### IMPURITIES IN WATER.

THERE is a startling difference in the purity of the water supplied to various towns in this dom. The report of Professor Frankland, of kingdom. the Royal College of Chemistry, shows that the water supplied to London, tested by samples drawn in April, ranged from 28.4 tons of solid impurity in the New River water to 42 tons in 100,000 of the supply of the Kent Company. In Bristol, samples drawn in February showed 28.66 tons of solid impurity in 100,000 tons supplied by the Bristol Waterworks Company; and in the supply furnished at All Saint's-lane no less than 127-28 tons. At Manchester, sample taken in June, there were only 6.2 tons of solid impurity; at Lancaster, in November, only 4.58 tons; Preston, in August, 12:44 tons; Newcastle, in September, 23:40 tons; Glasgow, in July, Loch Katrine water, only 3 tons Edinburgh, in September, the Crawley Burn, the Swanston, and the Colinton water, ranging from 11.28 to 14.10 tons; the Coniston water, 22.58 tons; Dublin, the Vartry water, brought from a distance of 30 miles, only 6:34 tons; Cartan's pump water, from the most used of the Dublin wells, 81 62 tons. It will be observed that water is supplied to Lancaster, Manchester, and Glasgow of very much greater purity than any that can be had in London.

#### RICKARD AND PAUL'S AMALGAMATING MACHINE.

T is estimated that the average amount of loss sustained by the different gold and silver mining companies, by the present systems of amalgamation, does not amount to less than 50 per cent. of the assay value in gold ores, and from 30 to 40 per cent. in silver. Taking into consideration that the United States of America is now producing £15,000,000 annually, while Australia furnishes nearly £6,000,000 more, it follows that if the present rate of loss can only be reduced by 10 per cent, the yearly saving of precious metals in these countries alone would amount to £2,100,000. But more than this saving, we are informed, is effected by the machine which forms the subject of the present notice. This apparatus is the invention of Messrs. Rickard and Paul. mining engineers, and is now being brought out by a company having their offices in Great Winchester-street Buildings, City. The first of these machines has been manufactured by Messrs. Gwynne and Co., of Essex-street, Strand, and was recently shipped to Chili. From an inspection of per ton. After half an hour's treatment in the this apparatus we are enabled to give the following machine, a sample of the tailings was taken, which,

particulars. Fig. 1 of our engraving shows a front view, partly in section, and fig. 2, an end view of the machine, which consists of a trough of galvanized iron, about 8ft. long and 4ft. wide, mounted on a timber framing or on brickwork. In the trough is a screw formed of a series of copper plates fitted on a shaft. These plates just dip into the bath of mercury, and keep it continually clean and fit for picking up the particles of gold. The screw is driven by belting, as shown; there is a raising catch and handle for lifting the screw out of the tank. In fig. 2 is shown a jockey beam for taking up the slack of the driving strap when the screw is lifted, a weight being attached to the end of the hanging chain.

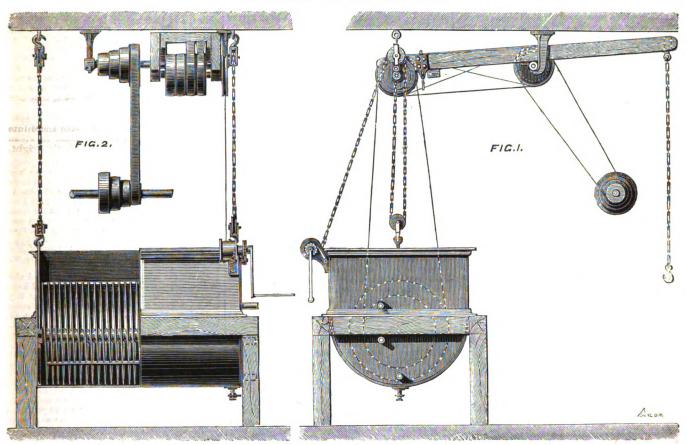

In operating with this machine, the copper plates are first cleaned with a little sand and dilute sulphuric acid. Each plate is washed in elean water as soon as the surface is perfectly bright, and immediately afterwards, the sodiumized mercury—made in the proportion of 1 part of sodium to 1,000 parts of mercury—is applied. As soon as the plates are completely covered with mercury, they are fitted on to the screw flanges and slipped on the axle, so as to form a continuous screw. means of a clamp attached to each plate, and three cross bars of wrought-iron running the entire length at right angles with the blades. cross bars assist also very materially in the agitation of the contents. 50lb. to 100lb. of sodiumized mercury are then introduced into the trough, and the screw lifted in and fitted at about 1-8th or 8-16ths of an inch from the bottom, so that the edge of each screw plate dips about 1-4th of an inch in the mercury. The charge of ore and water is then put in, the ore having been previously ground to such a fineness that it will pass through The screw a sieve of 60 holes to the linear inch. is then put in motion at the rate of from 70 to 100 revolutions per minute, and reversed every two or three minutes, or oftener, if it is found the ore travels too fast from end to end. This backward and forward action of the screw dashes the particles of ore, with violence, first on one side and then on the other of each amalgamated screw plate, which soon becomes coated with gold or silver amalgam, the excess of which flows off and mixes with the fluid mercury at the bottom of the trough or tank. If the contents are heated by steam or by setting the machine over a fire like a boiler, the amalgamation will be accomplished in a much shorter time; although the inventors state that they have had excellent results with cold water—some 86 per cent. assay value of gold in half an hour's working. The addition of 1 or 2 per cent. of salt in gold, and a larger proportion in silver ores, with or without sulphate of copper, is, in addition to application of heat, attended with beneficial results, results, by intensifying the electro-chemical action of the machine.

When the amalgamation is complete, after first drawing off the mercury or elevating the screw, the charge is run off by the plug holes, provided in the side of the tank, one at a time, commencing at the top (the motion of the screw being reduced to allow the mercury to settle), and run into settling vats, or over appliances for concentrating amalgam and sulphides from tailings. The mercury has to be fortified from time to time (every 4, 8, or 12 hours), by the introduction of a little solid sodium amaigam, in poular, 3 parts sodium to 97 parts mercury. The propormercury in the trough. The fluid mercury can be examined by means of the small iron tap at the bottom of the tank from time to time, and drawn off as often as may be considered desirable, when it is strained, distilled, and bullion smelted in the usual manner.

We are informed that from numerous experiments which have been made with this machine in the presence of gentlemen of eminent position in the mining world, it has been proved that the loss has, by its action, been reduced from 50 to less than 20 per cent. in the case of gold ores, while its action has been equally effective with silver slimes (from the Comstock lode, Nevada, United States), which at the present moment are allowed to run to waste in enormous quantities without any effort being made to obtain their precious contents, owing to the defects of the machinery now in use. The following results from an experiment made on January 21 last, illustrate in a very forcible manner the very rapid and effective action of the machine. The ore operated on was from the Chontales Mines, in Nicaragua, and before amalgamation assayed 502. 14dwt. 8gr. of gold

# AND SILVER AMALGAMATING MACHINE.

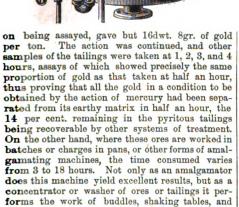

BY MESSRS. RICKARD AND PAUL.

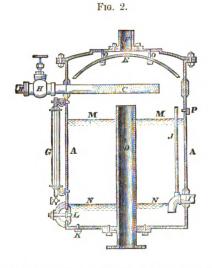

#### FEED-WATER HEATING APPARATUS

BY MR. H. N. WATERS.

other more expensive machinery, in a most rapid and inexpensive manner. The machine has also the advantage of being portable, so that it can be

mules, if necessary, in mountainous countries. These conditions, together with the above results, point out this apparatus as one likely to have a great influence in promoting the commercial success of gold and silver mining enterprise.

# WATER'S FEED-WATER HEATER!

 $\mathbf{A}^{\mathrm{N}}$  important invention, which has been recently patented in Europe and America, has just been submitted to our notice. It is a feed-water heater, the inventor of which is Mr. H. N. Waters, of Hartford, Connecticut, and appears to be one of the most valuable of the recent improvements for economizing fuel and increasing the durability of steam generators. It is applicable to all forms of boilers, and is designed especially for those where non-condensing engines are used. Our engraving shows at fig. 1 an elevation, and at fig. 2 a section taken to pieces and conveyed to its destination, on | of this apparatus. A is the reservoir for the heated

water; B the pipe for bringing water into the heater; C the sprinkler, through which the water is forced in fine jets; D the pipe through which the exhaust steam enters; E is the deflector, which is concave and circular shaped, for holding the steam for an instant in contact with the jets of water from the sprinkler; F is the exhaust pipe through which the surplus steam escapes; G the glass gauge, showing the height of water in the heater; H the valve by which the engineer regu-lates the supply of water for the heater; I the feed pipe, conveying the heated water to the boiler pump; J is an air pipe, connecting with the feed pipe I, for arresting the flow of water to the boiler pump when reduced to the line N, thereby preventing oil, tallow, and all substances retained in the oily scum floating on the top of the water from entering the boiler. K is a plug for inserting a pipe if needed, for carrying off sediment, and for drawing off the water in ease of exposure to freezing; L is a hand hole, for cleaning the heater; M the highest point of water line; N the lowest point to which the boiler pump can reduce the water; O O are bolts by which the deflector is water; O O are bolts by which the deflector is attached to the top of the heater; and P is a plug for the overflow pipe, if required. The exhaust steam from the engine enters through the pipe D, and comes in direct contact with the cold water from the sprinkler, instantly heating it to the boiling point, 212deg. A portion is condensed and forms a part of the supply of water required for the boiler, while the surplus steam passes off dry around the deflector and escapes through the pipe F. pipe F.

This apparatus, although simple in its arrangement, accomplishes a large number of important results. At the time we write it is not in use in England, having only just arrived here from America. In the States, however, it has been adopted in several important works, and is giving excellent results. In Hartford, Conn., we understand that every steam user, except one, has adopted it, the exception being a manufacturer who had applied a costly apparatus just previously to the appearance of Mr. Waters' heater. From its working in America it is stated to have been proved to effect the following results:—It furnishes the boiler with a full and steady supply of thoroughly heated water, raised to the boiling point (212deg.) by means of the exhaust steam, and without producing any back pressure on the engine. It keeps the boiler free from incrustation

and sediment, lime and other impurities in the water being separated from it and retained in the heater, leaving the water soft and pure as it enters the boiler. It is reported to save from ten to twenty-five per cent. of fuel, first, by using exhaust steam for heating the feed water and furnishing the boiler with a regular supply at 212deg.; second, by relieving the engine of the back pressure produced by other heaters; and, third, by purifying the water before it enters the boiler. It saves the boiler by keeping out all sediment, and by preventing the sudden and unequal contraction and expansion of the boiler, which takes place when cold or partially heated water is introduced. It furnishes an invaluable safegard against explosions. A full and constant supply of thoroughly heated feed water enables the engineer to maintain a uniform and proper height of water in the boiler, entirely obviating all necessity for stopping the boiler pump on account of low fire, and removing all temptation to permit the water in the boiler to become reduced to a dangerous point. It increases the capacity of the boiler, by the reason of the water being introduced at the boiling temperature. The condensation of steam which takes place in the heater furnishes an important proportion of the water required for the boiler; hence ensues an economy of water. All oil or tallow used in the cylinder of the engine, and all floating impurities which may be contained in the water, are retained in the heater and prevented from entering the With all these practical advantages, with the fact of its success in the United States before us—as evinced by testimonials from well-known firms there—we can entertain no doubt that it will prove a formidable rival to other systems in use. We hope shortly to be able to report upon the working of one of these heaters; in the meantime, we refer our readers to Mr. Theo. G. Ellis, of No. 62, Dorset-street, Salisbury-square, Fleet-street, to whom we are indebted for our particulars.

### ON THE WISCONSIN METEORITES.\* By Mr. J. L. Smith.

THE following paper is on a new meteoric iron —the Wisconsin meteorites—with some remarks on the Widmannstättian figures, by J.

Lawr nee Smith, Louisville, Kentucky. These meteorites were first brought to my notice by Mr. L. A. Lapham, of Wisconsin, and his attention was called to them by Mr. C. Daffinger, secretary of the German Nat. Hist. Society of Wisconsin. They were discovered in the town of Trenton, Washington county, Wisconsin, and I have called them the "Wisconsin moteorites." Up to the resent time, fragments have been found, indicating present time, fragments have been found, indicating that these meteorites were of the same fall and separated at no great elevation. They were found within a space of ten or twelve square yards, very near the north line of the 40 acre lot of Louis Korb, in latitude 43deg. 22min. N., and longitude \$8deg. 8min. west from Greenwich, and about 30 miles north-west of Milwaukee.

They were so near the surface as to be turned up with the plough; they weigh 60lb., 16lb., 10lb., and 8lb. respectively, and present the usual pitted and irregular surfaces.

The largest of the meteorites, in its extreme dimensions, is 14in. long, 8in. wide, and 4in. thick, weighing 62lb. Its specific gravity is 7.82, and composition-

A polished surface when etched gives wellmarked Widmannstättian figures. There is something, however, peculiar about the markings on this iron, which is doubtless common to other irons, but which has heretofore escaped my ebservation, and I cannot discover, in a hasty investigation, that it has been noticed by others. My attention was called to this peculiarity by Mr. Lapham, on a slice of the meteorite I sent him etched; should these markings be entitled to a separate notice, I propose calling them Laphamite markings. The little drawing accompanying this. which is on a somewhat exaggerated scale, will show what they are.

The Widmannstättian figures are a, bright metallic, with convex ends and sides; b c, of a darker colour, are the other markings, usually smaller and with the sides and ends concave. The

\* "American Journal of Science and Ast."

material of which these dark figures are composed seems to have enveloped the lighter coloured portion, which serves to make the dark lines so beautifully conspicuous. A good pocket glass will show that the darker figures are striated, with lines at right angles to the bounding surfaces. When the figure is nearly square, the lines extend

from each of the four sides, but when much elongated, as at c, they are parallel with the longer sides. Often these lines do not reach the middle of the figure, where only a confused crystallization can be detected. In the interior of the elongated figures, the lines are quite irregular, often running together, and showing a striking resemblance to woody fibre. The nature of these markings may woody nore. The nature of these markings may be easily understood. They indicate the axes of minute columnar crystals, which tend to assume a position at right angles to the surface of cooling. These markings may have been observed by others; and as soon as the subject can be examined on other irons, a better conclusion can be formed.

# INSTITUTE OF BRITISH ARCHITECTS.

THE annual meeting of the Royal Institute of British Architects was held on the 3rd inst., British Architects was held on the 3rd inst., when the council submitted their report, from which we gather with satisfaction that the affairs of the Institute—whether in regard to the steadily increasing numbers of its members, the condition of its funds, or the extent of its operations, continue to prosper. Since the last annual report was issued, 26 associates and 12 fellows (of whom 9 were previously associates) have been elected. It unfortunately became necessary, before the close of 1868, to withdraw the names of 8 defaulters (5 fellows and 3 associates) from the Institute list, which has further been diminished by the death of 6 fellows and 2 associates, and by the retirement from memand 2 associates, and by the retirement from mem-bership of 2 fellows and 2 associates. But even after these material reductions, the present number of fellows is 264, and of associates 244, making a total of 508, or 10 in advance of the previous official year. In other classes of membership the numbers are as follows:—13 honorary fellows, 9 honorary members, and 78 honorary and corresponding members, making, with ordinary fellows and associates, a total of 608 members. There are also 10 contributing visitors, 9 students, and 10 temporary students.

In regard to finance, the balance of funds in hand at the close of 1868 (£86 13s. 6d.) may seem, at first sight, small, as compared with previous years. But it is explained by the circumstance that a large But it is explained by the circumstance that a large number of cheques drawn in 1867 were not presented until January, 1868. The expenses of last year were, moreover, exceptionally heavy. The cost of repairs and fittings alone amounted to £118 11s. 4d. The generosity of the President, which has hitherto enabled the Institute to meet the expenses of the annual conversazione, was last year directed to another object. The President's munificent donation of £500 has been entirely expended in the purchase of books for the library, and the cost of the conversazione was paid out of the ordinary funds. When these circumstances are taken into consideration, it will be seen that the state of finances at the

the City, may be mentioned as an instance in which the timely intervention of this committee has been successful.

The question of artistic education for architects, after a lapse of some years, was again revived at the last annual meeting of 1868. The subject is the last annual meeting of 1868. The subject is still engaging the careful consideration of that committee, and their report is shortly expected. In partial connection with this subject, it should be borne in mind that the council, feeling that the scheme of a voluntary architectural examination had not met, of late years, with the response which was at first anticipated, appointed a committee to reconsider that scheme, and in consequence of its recommendation passed several resolutions, which were submitted to, and adopted by, the special general meeting held on the 5th of April.

A voluntary subscription was opened in 1868 by

meeting held on the 5th of April.

A voluntary subscription was opened in 1868 by the Institute, in aid of the Palestine Exploration Fund. Upwards of £50 was collected for this object, and forwarded to Mr. G. Grove, hon. sec. to the fund. Additional interest will no doubt be felt in this undertaking from the fact that Professor Donaldson, P.P., hon. sec. F. C., has since become officially connected with it, and in the autumn of least year, started for the Holy Land and signed the Donaldson, P.P., non. sec. F. C., has since become officially connected with it, and in the autumn of last year started for the Holy Land and joined the party of exploration. His letter, dated 21st December, 1868, and published in the Institute transactions, has already given some information on this head, and no doubt much more may be expected from the same source. Another letter from that gentleman, dated from Rome, on the 3rd of March, 1868, refers to many important architectural works now being carried on in Italy.

Among the honours conferred at home and abread on members of the Institute, has been that of knichhood by her Majesty on Sir Matthew Digby Wysit. F.S.A., while four other fellows—vix., Professor Donaldson, P.P., hon. sec. For. Cor., Messrs, G. G. Scott, R.A., George E. Street, A.R.A., and A. Waterhouse, have been elected honorary members of the Imperial Academy at Vienna.

In conformity with the order of rotation suggested in the report of council, dated 28th January, 1867, the Royal Gold Medal for 1868-69 has been awarded to "a foreigner, not being an architect," in the progress of Redin, the

awarded to "a foreigner, not being an architect," in the person of Professor Lepsius, of Berlin, the the person of Professor Lepsius, of Derin, the learned author of many treatises on art and archeo-logy, and of the splendid work on Egyptian and Ethiopian antiquities, a copy of which was presented to the Institute by his late Majesty Frederick William of Prussia. The council have satisfaction in finding that their recommendation of Professor Lepsius for this honour has met with the general approval of the Institute, and with the sanction of her Majesty.

# A NEW TRACTION ENGINE.

THE Ames Plough Company are now testing in Worcester, U.S., a combined traction and stationary steam engine, which they have built for some parties on the Parcific coast. It weighs about 18 tons, and as a stationary power may be used for sawing lumber the parties of the parti and as a stationary power may be used for sawing lumber, thrashing grain, pumping, hoisting, hauling, or for any other purpose to which steam power is adapted, as well as to move itself from place to place. The boiler is upright, about 7ft. long and 3 in. dismeter. One end of the bed of the engine is belted to the boiler about midway, and extends rearward about 6ft., and rests upon the axles of the rear wheels. The crank shaft, with a 6-inch crank, is situated across the rear end of the bed. One end of the shaft carries afty and belt, wheel about 4ft, diameter: upon the the rear end of the bed. One end of the shalt carries a fly and belt wheel about 4ft. diameter; upon the other end of the shalt is a pinion which works the traction gearing, which consists of an intermediate between the crank shaft and rear axle. This intermediate shaft carries a gear wheel about 2ft. diameter, driven by the pinion on the crank shaft, and a heavy pinion which drives a gear wheel about 5ft. diameter another object. The President's munificent donation of £500 has been entirely expended in the purchase of books for the library, and the cost of the conversazione was paid out of the ordinary funds. When these circumstances are taken into consideration, it will be seen that the state of finances at the close of 1868 may be reckoned not only satisfactory but even prosperous.

The necessity for a careful examination of the Metropolitan Buildings and Management Bill, suggested at the ordinary general meeting on the 20th January, 1868, led to the appointment of a select committee on the subject, by whom the bill was considered, clause by clause, during many sittings. Their final report was submitted for the approval of a special general meeting held on the 1st of February, 1869, and, after a few amendments, was forwarded to the Metropolitan Board of Works, in accordance with a resolution of the special meeting, and at the request of the Board itself.

The committee for the Conservation of Ancient Monuments and Remains, has, happily, had but few instances of threatened destruction or neglect brought before its notice within the last twelve months. It has, however, tendered its advice on some matters of importance, and generally with a satisfactory result. The preservation of the Church of St. Mary Somerast, in Thames-street, one of the capacity of 2-horse power, or less, will propel 18 tons, or any other weight, from Boston to Cali-

fornia on the common roads, provided it is applied to suitable gearing, and has time enough; and an engine capable of driving one of those huge threshing machines, used by some of the Western farmers, is capable of moving itself and overcoming considerble elevations at a fair pace, on ordinary roads -" F. G. W.," in the "American Railway Times." able

CASTING STEEL UNDER PRESSURE BY USE OF GUNPOWDER.

CASTING steel under high pressure, by means of gunpowder, is thus described by the inventor. It is well known, that cast steel run into moulds is subject to blister, and is otherwise porous, which defect reduces considerably its toughness. In order detect reduces considerably its toughness. In order to give this metal its requisite tenacity, it is subsequently reheated, and then rolled or hammered. A writer in "Van Nostrand's Magazine" says:—As many articles, such as cannon, cannot be treated in this manner, I have devised to submit them to a high pressure, while in a liquid state, inclosed in their same moulds, maintained in iron flasks. For this purpose impediately after wavelengths. high pressure, while in a liquid state, inclosed in their same moulds, maintained in iron flasks. For this purpose, immediately after running a cannon, I cover hermetically the head by a metallic cap, by means of bolts or other devices attached to the flask. This cap is fitted in its centre with a vertical pipe, and provided with a cock at its lower extremity, while its upper extremity is closed by a washer pressed by a bolt, in such a manner, as to act as a safety valve. Before attaching the cap, at, supposing, one inch from the surface of the liquid metal, I introduce in the vertical pipe, and between the cock and the washer, a charge of about one quarter of an ounce of a powder, prepared in the proportions of eighty parts of saltpetre and twenty parts of charcoal. On opening the cock, this powder falls on the metal, ignites and engenders about one-third of a cubic foot of gas at 3,000deg. Fah. These gases exert on the liquid metal a pressure which is transmitted throughout the entire mass, thereby condensing the same and expelling the blisters. The effect thus produced is equivalent to the pressure of a head of liquid metal 90ft, high, admitting that the capacity between the cap and the surface of the metal contains thirty cubic inches. By making the flasks sufficiently sthirty cubic inches. By making the flasks sufficiently strong, the charges of the powder may be varied, so as to produce by its ignition a uniform and general pressure, which is preferable to the partial, irregular, and momentary action of a hammer.

# Tegal Intelligence.

COURT OF COMMON PLEAS.

May 8.
(Sittings in Banco, before Justices Willes, Smith,

and BRETT.)

EDMUNDS v. GREENWOOD AND ANOTHER. thought the notorious "Edmunds Scandal' had been well nigh brought to a peaceful end, as far as the public law courts were concerned, by reference to arbitration. It appears, however, that all is not settled yet to the plaintiff's mind, for on the present occasion Mr. H. Matthews, Q.C., applied on behalf of Mr. Edmunds for a rule to show cause why the rule which had been already granted should not be rescinded upon the ground that it had been drawn up contrary to the inten-tion of Mr. Edmunds, who would be precluded from going into many matters which he deemed

essential to his case. Mr. Justice Willes, after a short discussion, said that, as the Lord Chief Justice was a party to the rule, the learned council might as well attempt to move the Rock of Gibraltar as to get the Court to

interfere without his presence.

Mr. Matthews asked if he should mention the

matter again some other day.

Mr. Justice Willes suggested that as the Lord Chief Justice might not be in Court any more this term, perhaps the better way would be to make an

application to him personally.

Under these circumstances the application was of course not granted.

> ADMIRALTY COURT. May 11. (Before Sir R. Phillimore.)

THE BOECLIFF-JUDGMENT-A NOVEL POINT. THIS case raised a novel question, and which was now decided for the first time. The action was to recover damages for a collision, and before the arrest of the vessel part of the cargo was released. The vessel and the cargo belonged to the same person, and the question was, whether the freight on the whole cargo should not be brought into court and made liable for the collision.

Mr. E. C. Clarkson and Mr. Bayford argued the question, and the judgment was reserved.

His Lordship, in giving judgment, remarked on the novelty of the question, and decided that the whole freight was liable, notwithstanding a part of the cargo had been discharged.
Mr. Clarkson asked for costs.

Mr. Bayford hoped his lordship would not give costs. It was a novel question, and raised for the first time.

Sir R. Phillimore thought it was a case to be argued, and made no order as to costs.

Judgment accordingly.

# Correspondence.

ASSOCIATION OF FOREMEN ENGINEERS. TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR.—Your report of the discussion upon Mr. Rae's paper on "Iron Shipbuilding," at the Association of Foremen Engineers, intimates that I not only disapproved of certain patents, but condemned all patents. Permit me to say that I must have been misunderstood. What I intended to state was, that, in my opinion, every shipbuilder ought to be perfectly free to connect the keel and keelson of a ship with the stem and sternpost if he sees fit; and that the attempt to deprive him of this liberty, except upon the condition of paying a royalty to a patentee, appeared to me preposterous. I also added that, if patent claims were pushed to such extreme lengths as this, all patents, and the patent system itself, would be laid open to objection. Beyond this it was not my intention to go, as I have not yet weighed the advantages and disadvantages of the patent system with sufficient care to form a final judgment either way.—I am, Sir, yours. &c., May 11.

[The report of the proceedings referred to was furnished us by an officer of the Association of Foremen Engineers.—ED. M. M.]

FIVE heavy 9-inch guns, which, together with the carriage and platform, will weigh about twenty tons each, are being placed in the Hubbertson fort by the men of the Royal Artillery stationed at Pembroke. The work is just completed.

necessary to recommend, the Secretary of State for War has decided that the usual half-yearly exami-nations for admission to the Royal Military College, Sandhurst, subsequently to that in June next, will be suspended until further notice.

The Royal Naval Reserve is becoming, what it should be, a great fact. We understand ("Army and Navy Gazette,") on good authority, that 1,800 men at least have volunteered to proceed on the Whitsuntide cruise, and we hear that the Lords of the Admiralty have been surprised at the enthu-siastic manner in which their invitation has been received and accepted.

THE quantity of shipping for sale in the Port of Liverpeol now amounts to the enormous aggregate of 124,788 tons, thus classified:—Colonial built sailing ships, 39,510 tons; British built ditto, wood, 18,464 tons; ditto iron, 5,266 tons; foreign built, sailing ships, 10,943 tons; new sailing ships, iron and composite, 4,590 tons; screw steamers, 38,180 tons; paddle steamers, 7,835 tons.

THE Board of Trade have awarded a binocular THE Board of Trade nave awarded a binocutar glass to Captain A. Jacques Barbedeau, of the French schooner "Marie Eugenie," of Dalhout, for his services to the survivors of the crew of the barque "Emma," of Liverpool, whom he took from the wreck of their vessel, in the Bay of Biscay, after her "Bistantial The Norwagian barana "Fleatwing." collision with the Norwegian barque "Fleetwing, on March 7, 1869.

The Peninsular and Oriental Steam Navigation The Peninsular and Oriental Steam Navigation Company have announced an accelerated mail communication with Japan. Their steamers will henceforth run fortnightly from Hong Kong to Yokohama and vice versa direct, instead of via Shanghai, as heretofore. The Hong Kong and Shanghai mail service will be continued as at present. The gain by this arrangement will be five days on the homeward passage and two days on the outward passage.

Three days' official trial last week, on board the "Teaser" gunboat, of Mr. Vavasseur's steel 115-pounder gun and carriage, under the direction of Captain Hood, R.N., of the "Excellent," have proved their efficiency. The less weight, by nearly 1½ ton, of the steel gun, would be a great advantage in the armament of vessels of light draft, while the screwshaft compressor is undoubtedly a most valuable appliance for checking recoil, and especially for holding the gun in hand and bringing it up while running out in a seaway. running out in a seaway.

Last month, 21 vessels, of 19,000 tons, were launched on the Clyde, while during the same month in 1868 and 1867 the number of vessels and amount of tonnage launched were respectively 16 and 6,700 tons and 18 and 9,300 tons. The first four months of the year also compare most favourably with the same period in the two preceding years. In that period of 1867 the number of launches was 56, and the tonnage 43,600; in 1868 the number was 61 and 39,600 tons, while during the same period this year the number was 62 and the tonnage 60,400. The finest of the vessels launched last month were the steamship "Aurucania," of 3,000 tons and 600-horse power, built by Elder and Co. for the Pacific Steam Navigation Company; and the steamer "Silesia," 2,690 tons and 600-horse power, built by Messrs. Caird, of Greenock, for the Hamburg and American Company. Besides these, several heavy saling vessels of from 700 to 1,500 tons have been launched during the month. during the month.

MAJOR-GEN. SIR H. WILLOUGHBY ROOKE, C.B., K.C.H., formerly of the 3rd or Scots Fusilier Guards, died on the 2nd inst. at Pilston House, Monmouthdied on the 2nd inst. at Pilston House, Monmouthshire, at the advanced age of 86. The deceased embarked with the 3rd Guards for Holland in August, 1799, and was present in the actions of August 27, September 10 and 19, and October 2 and 6. In 1813 he again embarked with his regiment for Holland, and in command of the 2nd battalion was present at the advance to Antwerp, bombardment of the French fleet at Antwerp, and the attack on Bergen-op-Zoom. Also the campaign of 1815, including the battles of Quatre Bras and Waterloo. In recognition of his military services in the Netherlands he was made a Companion of the Bath, and in 1833 a Knight Commander of the Royal Hanoverian Guelphic Order. On attaining the rank of Major-General in the army, in July, 1830, he retired from the service. retired from the service.

Five heavy 9-inch guns, which, together with the carriage and platform, will weigh about twenty tons each, are being placed in the Hubbertson fort by the men of the Royal Artillery stationed at Pembroke. The work is just completed.

The "Lewiston Journal" reports that Daniel Frederick Bakman, supposed to be the last of the soldiers of the Revolution, died at his residence at Freedom, Cattaragus county, New York, April 5, at the advanced age of 109 years 6 months. Mr. Bakman entered the army just previous to the skirmish of Fort Plains, and took some part in that battle.

In view of the changes in the education of candidates for the army which the Royal Commission, now sitting, on Military Education, may consider it THE current number of the "Proceedings of the

# Miscellanea.

WE would direct the attention of our readers to the great flower show, which will be held in the Crystal Palace to-morrow—Saturday—when there will be attractions of unusual interest both to horticulturists and to the public generally.

MESSRS. WILLS are introducing into this country a granulated tobacco, which is made of various degrees of strength, its chief virtue being that in the process of manufacture all the fine aroma of the leaf is pre-

A NEW electric organ, erected by Messrs. Bryceson Brothers, in St. George's Church, Tuffnell Park, was opened on Saturday last. The quality of tone of many of the stops in this instrument is superb, and the advantages gained from the application of the system are very great.

THE number of Cornish pumping engines reported for March is eighteen. They have consumed 1,851 tons of coal, and lifted 14-3 million tons of water ten fathoms high. The average duty of the whole is, therefore, 52,000,000lb., lifted one foot high, by the consumption of 112lb. of coal.

THE conversazione of the Institution of Civil Engineers will be held at the House of the Institution, in Great George-street, Westminster, on Tuesday evening, the 25th inst. Those of our readers —who have novelties in science or art to bring before the public, will do well to communicate with the Secretary of the Institution without delay.

SOME idea of the severity of the weather in the mountainous districts of Cumberland and Westmoreland may be gathered from the fact that, in spite of the warmth of the sun's rays, these mountains are still covered with snow. The Furness Fells are also pretty generally covered with a coating some two or three inches in thickness.

AGRICULTURAL gatherings in France are becoming Agricultural gamerings in France are occoming as common as they are on this side of the Channel. Last week, a great meeting took place near the old cathedral town of Chartres, where a most important trial of ploughs came off. Upwards of fifty competitors appeared upon the field. The first prize, a gold medal and 200 francs, was carried off by a man sent from England by Messrs. Howard, of Bedford.

Some figures compiled by the Austrian Board of Some figures compiled by the Austrian Board of Trade, show the great increase which has occurred in postal communication, owing to increased facilities and more complete organization. In the year 1866, the number of letters which passed through the post-offices of Austria smounted to 356,906,622 and in 1867, it was 480,549,152, being an increase of over 1981 millions in one was a long 1231 millions in one year alone.

THE highest store rent paid in Broadway is that of E. S. Jaffray's dry-goods store, which bring 60,000 dollars. The highest hotel rent is that of the Fifth Avenue, which rates at 100,000 dollars per annum; but the most profitable of all the edifices on that magnificent street is Trinity Building. This is occupied by offices. It cost about 200,000 dollars, and rents for nearly one-half that sum annually.

WE ("London Scotsman") understand that Mr. James Monteith, of 38, Duke-street, St. James's, has invested with the Senate of the Glasgow University, the sum of £1,000, as a bursary fund, with the view of assisting students in attendance on the University, and encouraging the study of modern languages. The bursaries are to be three in number, each of the annual value of about £16, and tenable for three

THE researches which for five years have been carried on in Yorkshire, chiefly on the Wolds, by the Rev. Canon Greenwell, of Durham, and other archaeologists, are to be resumed this month. This summer the operation will be carried on on the Howardian range and on the moors, on estates of Major Stapylton, Mr. Fairfax, and Earl Feversham. The reassembling of the scientific diggers is looked to with much interest.

THE imports of Australian wool into the United THE imports of Australian wool into the United Kingdom have made a great advance this year, having amounted, to March 31, to 34,546,5161b., as compared with 11,454,298lb. in the corresponding three months of 1868, and 16,856,581lb. in the corresponding three months of 1867. For the whole of 1849, the receipts of Australian wool did not exceed 35,879,171lb., so that the imports are now nearly four times a large as they were twenty were since. times as large as they were twenty years since

THE "Carlsruhe Gazette" relates that an accident the other day befell the celebrated chemist, M. Bunsen. He had prepared a quantity of a com-M. Bunsen. He had prepared a quantity of a composition recently discovered, and had dipped his fingers in the vessel to see if the composition was dry, when that slight pressure sufficed to ignite the whole mass, and a flame arose which scorched the experimentalist rather severely in the hands and face. He is expected, however to recover in the course of ten days or a fortnight.

College Hospital, are at this moment, two under the care of Dr. Harley and Mr. Berkeley Hill, whose cases strongly exemplify the more than usual "severity of spring" this year. The one is suffering from frostbite, producing mortification of the finger; the other, from sunstroke, while playing in the sun on one of the hot days of last week.

The following is a return of the quantity of coal exported from Grimsby during the month of April:

To Belgium, 787 tons; Canada, 433; Denmark, 1,101; Egypt, 1,875; France, 3,694; Holland, 541; Hanseatic Towns, 1,583; Italy, 542; Norway, 160; Prussia, 257; Russia, 1,514; Sweden, 1,511; Spain, 723; Turkey, 819—total foreign, 15,540 tons; corresponding period 1868, 24,585 tons; coastwise, 4.492 tons; ditto 1868, 28,078 tons; decrease, 8,941 tons.

THE College of Surgeons of England, having accepted from Mr. Erasmus Wilson, F.R.S., the munificent sum of £5,000, together with a fine collecs and models, for the endowment of of diseases of the skin, the committee tion of drawings and models a professorship a professors professors of the skin, the committee appointed by the council, will, of Thursday next, present a scheme, which has been agreed upon in concert with Mr. Wilson, for the chair to be thus founded. It is believed that the first series of lectures in connection with this chair will probably be delivered by its founder.

The first two months of this year presented a sensible expansion in the value of our exports to the Australasian group of colonies, the total to February 28 having been £1,835.520, as compared with £1,470,247 in the corresponding period of 1868, and £1,059,426 in the corresponding period of 1867. The exports increased to Western Australia, Victoria, New South Wales, Queensland, and Tasmania; but they decreased as regards South Australia and New Zealand. Of the whole of the exports made to February 28 this year, nearly one-half went to Victoria.

A special ascent of M. Giffard's monter captive balloon took place yesterday, at the Ashburnham Grounds, Chelsea, which Mr. Glaisher attended, with the view of adding to our meteorological knowledge. The wind, however, proved too strong for observa-tions to be taken, and, although, the balloon attained an altitude of about a third of a mile, nothing practical resulted. Another ascent is proposed, and we hope, in our next, to furnish further particulars. In the meantime—having joined in the ascent—we may observe that a more perfect and safe arrangement of captive ballooning was never carried out, and we look forward with much pleasure to our next ascent.

MR. BESSEMER at present receives a royalty of £2 per ton for the use of his patent process, but in February next, we hear, he proposes to reduce the royalty to half-a-crown per ton. Now, as £2 per ton February next, we hear, he proposes to reduce the royalty to half-a-crown per ton. Now, as £2 per ton upon steel rails is equal to about £250 per mile of railway, it is expected that railway companies will be induced to defer all orders, as far as possible, until next spring, when this reduction of £1 17s. 6d. per ton will come into operation. If this should be realized, the summer and autumn will be to the iron-menture an idle energy and many furnaces will promasters an idle season, and many furnaces will pro-bably have to be extinguished. An effort is, however, being made to induce the patentee to avert this threatened dulness of trade, by making arrangements for the proposed reduction to come into force at once. Upon the success of these endeavours will depend in a great measure the prosperity of the iron works in West Cumberland and South Lanca-

THE last sheet of ice which was attached to the The last sheet of ice which was attached to the right bank of the Neva, and which barred the river in front of the Winter Palace at St. Petersburg, broke up on the evening of April 22. The commander of the fortress, followed by a great number of boats belonging to the river police, the Yacht Club, the Custom-house, and the watermen, then crossed the stream to the Imperial residence to announce officially to his Majesty that the navigation was open. The roar of cannon spread the news throughout the city, and the river hitherto so gloomy was suddenly covered with a large number of small craft moving joyously in every direction. Formerly, the commander of the fortress presented to the Emperor commander of the fortress presented to the Emperor on this occasion a cup filled with water from the Neva, and the sovereign, after tasting the liquid, returned the goblet full of pieces of gold. A fixed sum added to the functionary's salary has been substituted for the present.

THE coming exhibitions at Beauvais, which open on June 1, are likely to attract a good many English visitors. The occasion is the agricultural show of the eight northern departments of France, which presents special interest to English farmers and others from the similarity of soil and products with others from the similarity of soil and products with our own country, the beetroot cultivation at the present moment furnishing an interesting object of study. The additional exhibition comprises six groups—the fine arts and application of the liberal arts; furniture, tissues, clothing, &c.; products of extractive industry, raw and manufactured; machinery and processes of the useful arts; agricultural buildings and products; and horticulture. In the dry, when that slight pressure sufficed to ignite the whole mass, and a flame arose which scorched the experimentalist rather severely in the hands and face. He is expected, however to recover in the course of ten days or a fortnight.

The rigours of an English spring are thus referred to in the "British Medical Journal." Among the patients in the new children's ward of University in the hands and expected, however to recover in the course of ten days or a fortnight.

The rigours of an English spring are thus referred to in the "British Medical Journal." Among the patients in the new children's ward of University in the patients in the new children's ward of University in the hands and stript and products; and horticulture. In the centre of the exhibition building will be a large to the worm of the outer edge or edges of the main chair pulley. Patent abandoned.

special gallery is set apart for fine and retrospective art. Steam and water power are provided for ma-chinery in motion. One new feature deserves notice; the chief prizes will consist of works of art, one in each group, and the others of medals.

THE broad gauge, as regards the midland districts of England, is now a thing of the past, the Great Western Railway Company having ceased to run any broad gauge passenger trains between London and Birmingham or Wolverhampton. Travellers be-tween London and Shrewsbury or the North have no longer to change carriages either at Wolverhamp-ton or Birmingham, the trains now running through between Paddington and Birkenhead on the narrow gauge without any change whatever. Already, too, on the branch between Reading and Basingstoke, the on the branch between removed, thus converting that third rail has been removed, thus converting that line from a mixed gauge into an entirely narrow gauge line, and connecting the Great Western system with the London and South-Western Railway and the south of England. In addition to this, the whole of the broad gauge lines north of Oxford will immediately be taken up, removing in the midland counties the last trace of the system of one of the two great rival engineers, whose plans were so long hotly contested, and celebrated as "the battle of the gauges."

# Patents for Inbentions.

#### ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3265, 3285, 3292, 3297, 3307 BUILDINGS AND BUILDING MATERIALS—3279, 3288, 3291,

3264 E. A. RIPPINGILLE, Holborn-hill, W.C. Motive over. Dated October 24, 1868.

This relates, first, to novel combinations and arrangements

This relates, first, to novel combinations and arrangements of parts whereby the products of combustion, in addition to being employed to raise steam, are ultimately mixed with such steam, and employed in any suitable manner to obtain motive power. The direct products of combustion are caused to enter a chamber, forming part of or in close connection with a chamber, in which a number of plates and troughs are arranged in such manner that water, which is allowed to enter at the top of such chamber in suitable quantities, is caused to fall on to the uppermost plate or rough, from which it drops into the troughs or plates immediately below, and when such trough or troughs are filled with water, the water begins to fall on to the plate next below, and thence into the next trough, and so on, until it arrives at the lowermost troughs, whence it is allowed to fall through suitable overflow channels to the bottom of the chamber.—Patent abandoned. of the chamber.-Patent abandoned.

of the chamber.—Patent abandoned.

3265 J. SILVESTER, West Bromwich. Steam gauges
Dated October 24, 1868.

This relates to pressure or steam gauges, in which the
pressure is measured by means of a flat tube, closed
at both ends, and bent into a circular or nearly
circular figure. An arm is used of such a length that
when the tube is in its normal position they overlap
each other. A screw pin, constituting the axis of the
index finger, passes through the bush of the said finger,
and takes into one of the arms. On the under side of the
said bush is a slot in the direction of a radius from the
centre, on which the index finger turns, and in this slot a
pin on the end of the other arm engages.—Patent abandoned.

3266 W. DAWES, Leeds. Pulley block. Dated October 24,

Digitized by Google

2267 P. M. CRANE, Manchester. Sizeing cotton warps.

Dated October 24, 1868.

This consists in the employment of paraffin as a constituent in the formation of sizeing and dressing compounds for cotton materials, which substance may be added to any of the usual sizeing compounds; for example, a compound such as follows answers well:—Flour 2801b. (or I sack), tallow 1lb., paraffin from \( \frac{1}{2} \) per cent. to 2 per cent. of the flour employed.—Patent completed.

3268 W. HEASLER, Greenwich. Coating wire. Dated

3268 W. Heasler, Greenwich. Coating wire. Dated October 24, 1863.

Upon each end of a shaft, extending the whole length of the machine, toothed wheels are keyed, each being of the same size. The shaft on which these wheels are keyed carries a pulley, round which a band passes, driven from any prime mover, whereby rotary motion is communicated to the shaft, or it may be driven by hand. The toothed wheel on the further end of the shaft is in gear with another but smaller wheel on a shaft, revolving in and supported by a standard, and carrying a frame supporting a drum, round which the wire to be coated is wound. The other end of this frame is connected to a hollow shaft, through which the wire, after being first carried over a guide pulley, is led, the hollow shaft being supported by and revolving in a standard.—Patent abandoned.

3269 B. NICHOLL. Regent-street. Plastic composition. Dated October 26, 1868.

This consists in a species of scagliola, composed of chalk, ordinary cement, and, if desired, colouring matter, by preference mineral colours, according to taste. It has been found that 100 parts by weight of chalk to 50 parts of cement will give a good result, but the inventor does not confine or restrict himself to these precise proportions. This is to be mixed with water to the consistency of plaster, and spread out in the form of a sheet or thin layer to dry and harden. When thoroughly dried, the composition is to be broken up into fragments of irregular form and size, according to the effect to be produced. These fragments are subsequently mixed with a semifuld or plastic mixture of ordinary cement and chalk, which latter substance may be tinted as required by the addition thereto of any suitable colouring matter.—Patent completed.

completed.

3270 C. HARRISON and R. WILSON, Manchester. Indicating temperature. Dated October 26, 1863.

This consists in the use and application of a thermometer and spirit level, mounted parallel to one another, upon one arm of a balanced lever, working on pivots in the same manner as a scale beam, the other arm of such lever being geared to, or in connection with a simple or compound lever, which implings against the clapper of a bell, hereinafter described. This bell is actuated by a train of wheel or clock work, the moving power of which may be a weight or spring, but the clapper of such bell is prevented moving so long as the lever impinges against it.—Patent abandoned.

11.—Patent abandoned.

3271 J. Loader and W. H. Child, Finsbury. Rotary engines. Dated October 26, 1863.

A central shaft in a fixed cylinder has a crank throw, and the crank pin has a disc fitted thereon. This disc revolves against the inside of the cylinder. A radial or other piston or stop works through a slot in the cylinder, its face works through a stuffing box, and its inside edge is kept against the revolving disc by a spring or otherwise. The movement of the disc is epicycloidal.—Patent abandoned.

doned.

3272 W. A. LYTTLE, General Post Office, London. Electro-letegraphic instruments. Dated October 26, 1863.

The inventor arranges a straight row of lever keys to represent the letters of the alphabet or other desired signs, and he places a drum or cylinder in such a position that when the keys are depressed their ends shall touch or approach the surface of the cylinder in the same longitudinal line. This cylinder is fitted with the same number of projecting pins as there are keys, and the pins are distributed spirally from one end of the cylinder to the other. so that lines drawn parallel to the axis through each pin should divide the surface of the cylinder into as many equal longitudinal parts as there are keys.—Patent abandoned.

doned.

3273 W. E. Gede, Wellington-street, W.C. Gas burner.
(A communication). Dated October 26, 1868.

This consists in its receiving gas through the middle and air from beneath or at the sides, with the object of altogether doing away with the branches and the solderings or brazings. Especially if the largest possible holes or circular outlets, more or less broad, may be pierced in the burner, according to the degree of light required.—Patent completed.

eompleted.

3274 W. BOULTON, Burslem. Pottery. Dated October 26, 1868.

This consists in giving an eccentric or irregular motion to articles made by the jigger or whirler, which may be performed or carried into practical effect in the following manner:—Two oval or irregular pulleys or cams are fixed on the jigger or whirler spindle, the same to be brought in contact with a round or friction pulley, by a spring or balance weight, the carrier of the said round pulley being stationary; the neck and toe blocks of the jigger spindle being made to slide, give a motion to the spindle, according to the shape of the pulley on the said spindle.—Patent completed. completed.

3275 J. JONES and S. P. BIDDER, Mitcham. Breaking

3275 J. JONES and S. P. BIDDER, MICCIAM. Breaking mineral. Dated October 26, 1863.

This consists in effecting the breaking down of coal, stone, and other minerals, by means of either hydraulic power or by screw power combined with a wedging action, in place of effecting such operation by blasting, as is at present the case.—Patent abandoned.

present the case.—Patent abandoned.

3276 T. Speight and H. France, Bradford. Wool combing. Dated October 26, 1868.

This consists in dispensing with the interior comb or combs, and substituting in lieu thereof one or more barrel porcupine combs, or endless card, or pin belts, to work in conjunction with the said large comb, for cleaning the projecting ends of wool or other fibres fed thereto.—Patent completed.

3277 T.PREISTLEY and W. DEIGHTON, Bradford. Looms.
Dated October 26, 1868.
This relates to the picking motion, or the means of picking the shuttles in plain looms for weaving, and the patentees' object is to dispense with the picker spindles

now employed. A slot hole is formed in the bottom of each shuttle box, and the shank of the picker is formed to slide freely in the slot, with a T-head or projection under the box, to prevent the picker coming out of the slot when the loom is in action. Ordinary upright picking sticks are employed, which are hinged in line with the axis of the lay or lathe swords, and have them to project upward through the slots of the boxes, and also through slots formed in the pickers. Motion or action is given to the picking sticks by horizontal shafts, actuated by tappets, fixed on the low shaft of the loom, the said shafts having levers thereon connected by adjustable metallic rods or links suitably jointed, to allow the required duplex motion of the said picking sticks.—Patent completed.

3278 W. MORT. Fenchurch-street. Retricerating. (A

motion of the said picking sticks.—Patent completed.

3278 W. MORT. Fenchurch-street. Refrigerating. (A communication). Dated October 26, 1868.

This consists in an improved mechanical combination for obtaining cold by an application of the well-known natural law, that a reduction of volume of any permanent gas, and simultaneous removal of the sensible heat, caused thereby, results upon expansion in a capacity for a power of taking heat from the bodies with which it comes in contact. In the case of articles of food, they are placed in a thin metallic cylinder (metal being a good conductor), the metallic and the wooden cylinders being separated by a spiral or spirals, made of wood of sufficient thickness to form the ribs of two cylinders, great strength in which is ensured by bolting the two together through the wooden spirals. The gases are expanded in file space between the spirals, whereby the reduction of the temperature is accomplished, and after circulation are led back to the apparatus for recompression.—Patent completed.

3279 F. RANSOME, Queen-street Place, E.C. Preserving

apparatus for recompression.—Patent completed.

3279 F. RANSOME, Queen-street Place, E.C. Preserving stone. Dated October 26, 1868.

This consists, first, in applying in succession to the stone or other material to be treated a solution or fluid mixture of lime or baryta or other similar substance, and a solution of silica, by preference an alkali silicate. Second, in applying in succession a solution of superphosphate of lime and a solution of baryta, strontia, or lime, by preference, and alkali silicate.—Patent completed.

3280 A. M. CLARK, Chancery-lane. Scouring wool. (A ommunication). Dated October 26, 1868.

3280 A. M. CLARK, Chancery-lane. Scouring wool. (A communication). Dated October 26, 1868.

This relates to machinery for removing the grease from wool with the aid of plaster in powder. Cast iron or other frames are placed about 4ft apart. Drums or cylinders of about 3ft in length are each formed of half cylinders riveted together. Each drum is provided with sliding inlet and outlet ports, the outlet port being opened by the aid of racks adapted to the curve of the cylinders. The pinions have teeth on a fifth only of the circumference, for the purpose of raising the ports by the aid of racks, and allowing them again to fall when released from the teeth.—Patent completed.

3281 W. E. Gedge, Wellington-street, W.C. Manufacture of sall stones. (A communication). Dated October 27, 1868.

ture of salt stones. (A communication). Dated October 27, 1868.

The mode of manufacturing these "salignons," or salt stones or cakes, is as follows:—The crystals of sal gemma, a mineral salt, are first broken or powdered into pieces small enough to pass between two cylinders, which reduce them to powder. A certain quantity of water is then mixed with this pulverized salt, and it is put into wooden moulds, in which, by means of a powerful pressure, all the molecules are reunited. The drying then takes place, and by the rapid evaporation of the water, the salt crystallizes, and thus regains nearly all the hardness it possessed before the operation. The mode of using these salignons, or salt cakes, is as follows:—A small wooden box is made, into which the salt stone fits tightly, or is otherwise secured. This box is then nailed or screwed between the rack and the manger, giving it a horizontal position for horned beasts, and a vertical one for horses, as being that in which these animals may most readily lick the salt. A rectangular shape is given to these salt stones, cakes, or salignons, the dimensions varying at pleasure.—Patent abandoned.

3282 A. H. Smith. Clifton. Gas-heating apparatus. Dated

3282 A. H. SMITH, Clifton. Gas-heating apparulus. Dated

October 27, 1868.

The patentee constructs a square chamber, made of bricks, freclay, or any other suitable material. By means of an air shaft he introduces a current of air to act upon a series of ring burners; underneath or above these burners he employs a water cistern, made of fireclay. This cistern reaches above and below the burners. The encloses the whole of this with a bottle-shaped cylinder, made of fireclay. Over the top of this cylinder he places a dome, likewise made of fireclay, movable or fixed. The whole of the apparatus is covered with an iron grating fitted flush with the floor. The burner is supplied from an ordinary main, and lighted according to circumstances. This invention can be applied to an ornamental case, and fixed in any position above the floor, as may be required.—Patent completed. -Patent completed.

Ricel in any position above the floor, as may be required.

—Patent completed.

3283 G. ZANNI. Ironmonger-lane. Telegraph printing instruments. Dated October 27, 1868.

It is proposed to work electro-magnetic coils without the aid of the ordinary clockwork, whether driven by weights or by springs. The electro-magnetic coils employed are such as are in general use in electro-magnetic bell apparatus, and they work in connection with a battery or batteries and the earth, or with a compound magnet. Two sets of electro-magnetic coils are employed. The one set is for the purpose of giving action to drive the type wheel, and the other set acts to lock the type wheel and hold it correctly in position while the printing is taking place, and it also serves to bring down the block or presser upon the strip of paper, and thus causes the printing to take place. The type wheel is mounted upon an axis carried by the framing or case of the instrument, and also upon the same axis is mounted a ratchet wheel having as many teeth as there are characters or signs upon the type wheel, and this ratchet wheel receives a step-by-step motion from the action of one set of the electro-magnetic coils in the following manner:—Midway between two or more electro-magnetic coils is fixed a standard or support carrying near its upper end a pin or axis, upon which a horizontal bar or armature is mounted. This bar is caused to vibrate upon its axis to a slight extent in either an upward or downward direction, according as it is influenced by the one or other of the electro-magnetic coils, between which it is mounted. At

one end of the vibrating bar or armature just described a clawker or driver is carried, which, by acting upon the teeth of the ratchet wheel, gives motion thereto as well seems as are mounted upon the same axis. An arm attached to or carried by the vibrating bar or armature already described, serves to act upon a suitable brake for alternately making and breaking the circuit of the electric current of the one set of electro-magnetic coils and then of the other, and thus imparting to the bar or armature its vibrating action.—Patent completed.

3284 W. E. HICKLING, Spittlegate. Washing casks. Dated

3284 W. E. HICKLING, Spittlegate. Washing casts. Dated October 27, 1886.

The machine consists of a foundation carrying two standards, in the upper portion of which are bearings, in which the main shaft revolves. The main shaft consists of a wrought-iron box, which revolves horizontally in the bearings. In the middle of the said shaft (that is to say, at equal distances from the two bearings above mentioned) two arms project at right angles from the asid shaft, and on opposite sides therof. Upon each of these is arranged a cage or apparatus for holding the casts to be washed. These cages are free to revolve on the said arms, and are caused to revolve by means of the following mechanism:

—On one of the standards carrying the main shaft is fixed a bevel pinion, through the centre of which the main shaft revolves without moving the pinion, and on the bottom of each cage is fixed a bevel wheel, which gears with the said fixed pinion.—Patent abandoned.

2225 J. LITTLE Glasgow. Glass threaces, Dated October

3285 J. LITTLE, Glasgow. Glass furnaces. Dated October

3295 J. LITTLE, Glasgow. Glass furnaces. Dated October 27, 1868.

The object is to economize the fuel employed for heating glass furnaces, and the invention consists in introducing air inside the furnace for the thorough combustion of the fuel and its gaseous products, such air being proviously heated by passing through flues, constructed in the siege or floor and sides of the furnace, and which flues are heated simply by conduction through the siege or floor and sides from the furnace itself. One glass furnace may be provided with any convenient number of separate air flues. Each air flue is arranged in a serpentine or sigzag course, beneath a portion of the siege or floor on which the melting pots stand, and is then carried up close to the side of the furnace or melting chamber to a level above the tops of the pots, and at about the springing of the arched roof, and at that level the air is admitted from the flue into the chamber through a number of small apertures in the side wall. The inlet for the air into the flue is, by preference, arranged outside of the building, so as to be easily accessible for the adjustment of a damper or other appliance for regulating the supply of air.—Patent abandoned.

3286 J. B. O'HEA and W. BULLEN Greenwich. Firewards.

appliance for regulating the supply of air.—Patent abandoned.

3286 J. B. O'HEA and W. BULLEN, Greenwich. Firearms and cartridges. Dated October 27, 1868.

This consists in attaching a cup similar to, and answering all the purposes of, the metallic base to the fore end of the bolt, and using a paper cartridge containing its own ignition, the base of which is placed in the said cup or metallic base before the cartridge is pushed forward or entirely home into its place in the chamber by the bolt. The metallic cup is attached to the fore end of the bolt or piston by screwing or otherwise, in such a manner that as soon as it becomes deteriorated by use, and hence ceases to perform its function of preventing the escape of gas, it may be readily removed and replaced by another. The needle or striker passes through the centre of the metallic cup, and ignites the charge by striking against the fulminate contained in a cap, which is perforated and provided with a flange, and is placed in the rearend of the cartridge in such a way that, upon the explosion taking place, the flange of the cap draws out the base of the cartridge, and leaves the cup ready to receive another. Any other simple arrangement for extracting the base of the paper cartridge may be employed, or, if preferred, the base of the cartridge may be closed by a wad or plug of compressed or ungranulated powder, containing a patch of fulminate in the centre. The recess through which the needle passes is furnished with a disc or ring of india-rubber, or other suitable substance, which, at the moment of the explosion being compressed endwise, expands both internally and externally, and effectually prevents the escape of gas round the needle. In some cases, the ignition of the fulminate, when placed at the extreme base of the cartridge, may be caused by the simple percussion of a bolt or striker against the rear end of the cup.—Patent abandoned.

3287 G. FAJEN, Leighton-road, N. Ventitators. Dated October 27, 1868.

against the rear end of the cup.—Patent abandoned.

3287 G. FAJEN, Leighton-road, N. Ventilators. Dated October 27, 1868.

This consists of an apparatus made to the size of the internal part of a chimney, flue, or other opening of a circular, oval, or square construction. The apparatus is made of sheet iron, galvanized block tin, zinc, copper, or brass. On the external part there are steel springs fixed, of an elongated or globular shape; there are flaps or metal doors fitted and hung on hinges. The action of the springs on the flaps or doors are of sufficient power to hold the apparatus in position when placed in such chimney, flue, or other opening. The internal part of the apparatus is filled with a fan, screw, or worm, made of metal, and of any desired diameter, pitch of screw, or elevation thereof; this fan, screw, or worm is provided with a steel spindle, which is the centre with glass bearings, fitted on which it will rotate either in a vertical, horizontal, or in an efevated position.—Patent abandoned.

3288 W. D. Young, Edinburgh, Roofing. Dated Octo-

3288 W. D. YOUNG, Edinburgh. Roofing. Dated Octo-er 27, 1868.

3238 W. D. YOUNG, Editioria, 2007-19.

ber 27, 1868.

All the edges of the tiles or plates are bent over in the form of a hook, so that, when laid in place, they overlap, catch, or interlock into each other. The joints of the tiles or plates, by being so interlocked, form an effectual protection against rain or wind passing through. The tiles or plates may be fixed to the beams or frame by hooks or clips firmly secured to the beams or frame, the hook portion passing into and bearing upon the overturned or bent edges of the tiles or plates.—Patent completed.

8289 J. WALLACE, Glasgow. Dentistry. Dated October

27, 1868.

This relates, firstly, to the employment of aluminium as a substitute for other metals or materials used for dental purposes. The invention essentially consists in forming the plates and other parts to which artificial testh are connected of aluminium, the different pieces of which are castened together by vulcanite or other suitable material. Another part of the invention relates to engraving a design on the part of the plates next the flesh of the mouth, and by which they are more securely held in place than when formed plain or smooth.—Patent completed.

3290 E. T. VAN HECKE, Courbevole, France. Locomo tires. Dated October 27, 1868.

This consists in placing in the smokebox of a locomo

This consists in placing in the smokebox of a locomotive engine a screen or partition, so arranged as to compel the heat, smoke, and gases from the fuel to pass down wards nearly to the bottom of the smokebox before they pass out at the funnel, instead of their passing directly from the tubes up the funnel, as heretofore practised. The screen is formed of sheet iron of a suitable thickness. Its front is movable, and slightly inclined. It may be formed of one or two pleces, according to the construction of the interior of the smokebox, but in either case it is so arranged that it can be quickly opened or removed to allow of the tubes of the boiler being cleaned. The sides of the screen, which are only removed when the engine requires repairing, may be fixed to the tube plate in suitable manner.—Patent completed.

3291 J. JOHNSON, Chandos Chambers, W.C. Window

requires repairing, may be fixed to the tube plate in suitable manner.—Patent completed.

3291 J. Johnson, Chandos Chambers, W.C. Window frames. Dated detaber 27, 1868.

The barrels or drums are caused to rotate by cords, bands, or lines, rouning through suitable guides and passing down the window frames in the manner of ordinary roller blind cords, such cords, bands, or lines being secured to, and passing around, large pulleys or wheels attached to the barrels or drums for giving a certain amount of leverage, so that by pulling the cords at the sides of the frames, and thereby causing the large pulleys, and with them the barrels or drums, to rotate, the cords attached to the sashes or shutters will be wound around the barrels or drums, and the sashes or shutters consequently raised; while, on the barrels or drums being caused to rotate in a contrary direction, so as to unwind the cords, ropes, bands, or chains, the sashes or shutters being released, will descend by reason of their own preponderance over the sash weights, which latter are for this purpose made so as only partially to counteract the descending tendency of the sashes or shutters. The cords, bands, or lines, by which the barrels or drums are actuated, may be kept tightly drawn down the sides or linings of the window frames by adjustable pulleys or buttons held in position by spring catches capable of being slightly raised or depressed when requisite, so as to somewhat slacken the cords, bands, or lines, and thus permit the sashes or shutters to descend by their own weight, until the adjustable pulleys or buttons are again released, when the action of the spring catches will cause the cords, bands, or lines to be again drawn tight, and thus to instantly arrest the downward progress of the sashes or shutters.—Patent completed.

3292 T. Mordue, Newcastle. Steam botters. Dated October 27, 1868.

sashes or shutters.—Patent completed.

3292 T. Mordue, Newcastle. Steam botters. Dated October 27, 1888.

This invention is particularly applicable to compound marine engines with surface condensation, and where very high pressures and economy of fuel are required. The improved boilers consist of a main cylindrical portion, containing the usual tubes; also of one or more cylindrical or other shaped portions containing the furnaces; also of a combustion chamber uniting the furnaces; also of a combustion chamber uniting the furnaces is the tubes passing through the main portion of the boiler, then through the superheating tube or tubes placed in the steam chamber, and thence to the chimney or funnel. The water space surrounding the furnaces is connected to the main portion of the boiler by one or more water tubes, and also to the water spaces surrounding the combustion chamber.—Patent completed.

3293 R. Hamilton, Auchinheath, Lesmaghow, N.B.

chamber.—Patent completed.

3298 R. Hamilton, Auchinheath, Lesmaghow, N.B. Raileay chairs. Dated October 28, 1868.

This consists in making the chair in two halves, which are connected together by a hinge or other suitable connection under the rail. The jaws are both shaped to fit the web of the rail, and without the bottom of the rail touching, so that the rail is suspended, and the bottom does not become injured by striking the chair; whilst from the position of the hinge or connection, the downward pressure of passing trains tends to make the jaws grip the more firmly.—Patent abandoned.

grip the more firmly.—Patent abandoned.

3294 H. J. SANDERS, Brighouse. Regulating flow of liquids. Dated October 28, 1868.

This consists in an enclosed vessel or chamber having two or more inlets and one outlet to which pipes may be attached. The inlets are each provided with a valve which is capable of being adjusted to open more or less, according to requirement, by means of screw, cam or eccentric. This vessel may be formed with separate passages from the inlets to the outlet, and, by preference, one of such passages may be annular or concentric to the other, so that when the apparatus is applied to draw stale beer from one vessel or cask, and ripe or effervescent beer from another, the ripe may act as an injector to the stale. An ordinary beer pump may be applied to the outlet of this apparatus in the usual manner.—Patent abandoned.

3295 J. MORAN. Dublin. Bools and those. Dated Octo-

8295 J. MORAN, Dublin. Boots and shoes. Dated Octo-

3295 J. MORAN, Dublin. Bools and shoes. Dated October 28, 1868.

This consists in an improved mode of attaching the soles to the upper leathers of riveted boots and shoes. The invention is carried into operation as follows:—A drill or channel of about one-third the thickness of the sole is cut in the sole, near to the edge. This drill or channel is of sufficient size to hold the heads of the rivets, the rivet holes being made in the channel, and the rivets driven and riveted in the usual manner upon an iron last, so that when the sole is fastened to the upper, the rivet heads are at the bottom of the drill or channel, where they can readily be covered by turning down the leather raised to make the drill or channel, and the heads of the rivets will not be at all exposed to view, and will not be worn off until the sole is itself worn out or requires replacing—Patent abandoned.

3296 M. A. Soul, Finshury-place.

Permanent way.

Patent abandoned.

3296 M. A. SOUL, Finsbury-place. Permanent way.
(A communication). Dated October 27, 1868.

This invention relates, first, to the arrangement of improved parts of the permanent way of railways, and to the construction of certain of these parts, principally the sleepers and chairs, in cast iron, malleable cast iron, wrought iron, steel, or in fireclay or other earthy material; also to the combination of such parts with wood, as the holding or supporting parts of the permanent way, which is effected in such a manner as to ensure elasticity, stability, and economy, in such permanent way. Second, to a novel form of fish joint for uniting the ends of the rails, the fish joints being made in two halves in such a way that they can be held together by clamp or clip pieces of wrought or east iron or steel.—Patent completed.

3297 C. E. BROOMAN, 166, Fleet-street, E.O. Condensers.

3297 C. E. BROOMAN, 166, Fleet-street, E.C. Condensers.
(A communication). Dated October 28, 1868.
This consists in elevating the condenser above the water

level to a point above that at which the weight of the atmosphere will support a column of water, and connecting it by means of a pipe with the hot well, thus forming a syphon crowned with the condenser, of which the first pipe is the short leg, and the last the long leg. The exhaust pipe of the engine also discharges into the condenser. By this arrangement, the water of condensation is raised into the condenser by atmospheric pressure, and removed from it together with the condensed steam by gravity.—Patent abandoned.

3298 A. WILSON, Barrow-in-Furness. Metallic moulds.

is raised into the condenser by atmospheric pressure, and removed from it together with the condensed steam by gravity.—Patent abandoned.

3298 A. WILSON, Barrow-in-Furness. Metallic moulds. Dated October 28, 1863.

This consists in making metallic moulds for casting metals in such a manner that the entrance of air through the junctions of the parts of the moulds during the use of the moulds is obviated, and a sound casting thereby produced. The invention is particularly applicable to metallic moulds, made in two parts or halves, for casting steel ingots, but may also be applied to metallic moulds for casting other metals and articles, and also to metallic moulds made in more than two parts. The invention consists in the formation of a cavity at each of the junctions or joints of the parts of the metallic mould, and filling the said cavity with sand, fireday, or other fireproof material. By the use of the cavity described and illing material, a perfectly airtight junction is formed, and the entrance of air through the said junction into the metal cast in the mould is prevented. In making a mould for casting steel ingots, the inventor makes along the whole length and at the outside of the joints or junctions of the two parts of the mould an opening or cavity of the required size to hold the sand or other filling material employed. He covers the cavity at the junction by means of a metallic cover, strap, or plate, which is fastened in its place on the outside of the mould together, or by any other convenient mechanical arrangement. When the cavities described are filled with sand, wood, or other filling material, a core is formed along the whole length of the joints of the mould; or, instead of forming the cavity by making a depression on the outside of the junction of each half mould, and covering it by a cover, strap or plate, the cavities may be made in the balf moulds themselves either by casting them in the half moulds or fixing pieces to the half moulds. In this case, apertures or holes may be left to carry

3299 W. DAWES, Leeds. Pianofortes. Dated October 28,

Patent completed.

3299 W. DAWES, Leeds. Pianofories. Dated October 28, 1868.

This consists in substituting for the ordinary wood or cast-iron "frame" of the instrument, a compensating frame, so constructed, that it compensates for the alterations in length and tension of the wires or strings, through variations of temperature, by its own expansion or contraction for heat or cold, in a like or necessary manner or degree to the strings themselves, the amount of compensation being gauged or determined by the kind mixture or alloy of metal or metals employed in the frame, or by the quantity or proportion of zinc. brass, or other expansive metal used. Second, in a novel construction of soundboard for increasing the amount of vibration, and thereby improving the tone of the instrument. This is effected by the use of a double soundboard, constructed with a space of about lin between the front and backboards, and this soundboard is sometimes constructed with the back somewhat smaller in size or area than the front, and the two are firmly attached together, in such a manner, that this difference in size causes compression upon the frontboard, and tension upon the backboard, and thus increase the resonance and tone; and in some cases, this tension and compression is produced by a kind of lattice or open back of separate strips or bands, each one having the necessary amount of tension, by means of screws or wedges, as may be desirable. Third in the employment of a revolving or other mechanical movement actuated by the feet or otherwise, for prolonging the notes of the instrument, by a succession of extremely rapid blows or strokes upon the wires (or upon additional wires placed at the back of the instrument, either from the usual or ordinary hammers, or others, or both, such blows or strokes upon the succession of extremely rapid blows or strokes upon the succession of extremely rapid blows or strokes upon the succession of extremely rapid blows or strokes upon the prolong-ing the notes of the instrument, by a successio

contrary, with as much amoothness and connection as possible.—Patent completed.

3300 G. E. Donisthorps, Leeds. Packing for pistons. Dated October 28, 1868.

In order to form a steam or fluidight packing to a piston or gland, the inventor places around the piston or inside the gland, a flexible bag, of a ring form, and this bag he distends by putting it in connection with a small reservoir containing a fluid, which is maintained at a pressure exceeding the working differential pressure of the steam or other fluid with which the engine is worked by a piston or plunger forced inwards into it, by a weighted lever, by a spring or otherwise. The action of the lever should be so regulated as at all times to be a little above the working pressure in the cylinder at all parts of the stroke, especially when great expansion is adopted. In place of employing a bag, as above described, a groove might be formed around the piston or the gland, and this groove might be kept filled with fluid, under a pressure greater than the working pressure in the cylinder of the engine; the parts may either be made to fit together with sufficient truth to prevent too free an escape of the packing or lubricating fluid, or washers of leather may be placed on either side of the groove, to limit the escape of the packing and lubricating fluid. At the front of the groove around the piston or gland, split rings of metal may be placed, if desired, so that the rings shall be pressed outwards from the groove when fluid; these rings will also prevent too free an escape of the fluid from the groove around the piston or gland; the outer dismeter of the gland would have to expand, and, at the same time, the internal portion would have to contract, to effect a steamtight packing on the piston or defended to the processed outwards. Tooth brushet. -Patent completed.

3301 P. B. Cow and J. Hill, Cheapside. Tooth brush Dated October 28, 1868.

Dated October 28, 1868.

There has lately been introduced into the market a porous form of vulcanized india-rubber, called india-rubber sponge. According to this invention, this material is used as a substitute for bristles in the manufacture of brushes. The inventors cement or fix a piece of india-rubber sponge to a back or handle, and form grooves on

the surface of the spongy material to obtain a brush-like action.—Patent completed.

3302 C. KELSON, Lombard-street. Horse collars. (A com-unication). Dated October 28, 1868.

2302 C. Kelson, Lombard-street. Horse collars. (A communication). Dated October 28, 1868.

This consists in constructing collars hollow, and of a semi-shell shape form. The collar is rendered much lighter, and its elasticity greatly increased, by constructing the same with numerous perforations. These may be either circular, oblong, or of any other form that the taste of the manufacturer may suggest. Within the concavities of the collar plates are secured the rein eye and also the trace clip. These may be secured by independent bearings or attached to a hamebow in the ordinary manner, in which case, the hames are permanently secured to the collar.—Patent abandoned.

3303 W. PROWETT, Gillingham. Knitting machines. Dated October 28, 1868.

In constructing a knitting machine, the inventor employs In constructing a knitting machine, the inventor employs bearded needles, similar, or nearly so, to the ordinary hosiery needles, and he mounts them on slides, which are actuated in such a manner as to give to the needles an endway traverse. The inventor generally makes the machine double acting, by mounting needles on each end of the slides; the machine, in this case, produces simultaneously two fabrics, one at the front, the other at the back of the machine. The needle are, by preference, worked in pairs, so that each slide carries four needles. The slides are arranged slide by side in suitable guides; their number depends on the width of the work the machine is required to make, and on the gauge of the machine.—Patent abandoned.

depends on the width of the work the machine is required to make, and on the gauge of the machine.—Patent abandoned.

3304 J. J. Tongur, Southampton-buildings, W.C. Fire alarum. (A communication). Dated October 28, 1868.

This consists in the combination of two thermometers having an unequal sensitiveness, and so arranged as to permit the warning or signal apparatus to accomodate itself in an automatic manner to the normal variations of the temperature in which the apparatus is placed without such signal or warning apparatus being brought into action, the thermometers being so arranged that a warning signal or indication will always be given with promptitude, and, consequently, in an efficacious manner every time the temperature changes suddenly, from an accidental or other cause, such warning, signal, or indication being continuously maintained when the temperature of the place in which the apparatus is placed has risenabove a certain predetermined limit. The two thermometers employed, either or both of which may be liquid or metallic, are, according to this invention, so arranged that the one is very sensitive and indicates almost instantaneously the degree of temperature of the situation in which the apparatus is placed, the other thermometer taking a longer time to indicate a corresponding temperature, and so establish an equilibrium between the two thermometers, which, by preference, are so constructed as to travel over the same distance for each degree of heat indicated. The two thermometers are placed in connection with the two poles of an electric or galvanic pile or battery, the two thermometers are placed in connection in incomplete, but should any sudden increase of temperature occur, the sensitive thermometer operating more rapidly than the less sensitive one, acts by means of suitably arranged contrivances, to place the two thermometers in electric communication, and so complete the electric circuit, which will then, by any of the well-known means, set in motion warning signals, alarums, or other i

pleted.

3305 M. Brison, Hinde-street, W. Shaft couplings. (A communication). Dated October 28, 1868.

This consists in constructing a shaft coupling with an internal split, sleeve, or tube to fit the ends of the shafting, the sleeve having external conical ends, the larger diameter being in the centre, and the smaller at the ends. Each end of the sleeve is fitted with a compressing or tightening shell, furnished with means for acrewing their internal ends together, which firmly presses the internal split sleeve to the shafting, owing to its conical shaped ends. The internal split sleeve is constructed sufficiently thin and light in its cross section to be compressed concentrically to fit shafts of slightly varying diameters, and the outer or compressing shells are so constructed that the strain falls equally on each end of the coupling, and they are so connected that they represent the continued strength of the shafting through the coupled joint.—Patent completed.

3306 B. DORSON and J. CLOUGH. Bolton. Preparing col-

3306 B. DORSON and J. CLOUGH, Bolton. Preparing cot-in. Dated October 29, 1868.

3306 B. Dorson and J. Clough, Bolton. Preparing colton. Dated October 29, 1868.

The inventors employ a balanced lever, the upper end of which forms a guide to guide the fibres in passing from the front drawing rollers to the trumpet mouth placed above the calender rollers which deliver the sliver to the can or coiler, or other receptacle. The lower end of the lever takes into a slot in the end of a vibrating rod, which is connected to and actuated by the usual rocking shaft of the back stop motion. As long as the proper quantity of slivers is passing to the calender rollers the slivers hold the lower end of the balanced lever clear of the vibrating rod, and the machine continues its work, but if one or more slivers break or the quantity of fibres is otherwise deficient, the upper end of the balanced lever rises and the lower end drops, and is then struck by the end of the slot in the vibrating rod, the lower end of the lever coming against a stop in the standard supporting the balanced lever. By this means the rod is stopicd, and the rocking shaft being also arrested, moves the driving strap from the fast to the lower pulley, in the usual manner. When the end or ends have been pieced up, and the frame is again started, the end of the vibrating rod comes against the lower end of the balanced lever, and replaces it in its proper working position. The balanced lever can be adjusted by a regulating screw connected to the lower end of the said lever.—Patent completed.

3307 R. MELDRUM, Cupar, N.B. Utilizing waste steam.

3:907 R. MELDRUM, Cupar, N.B. Utilizing waste steam. Dated October 29, 1868.

This consists in a chamber or chambers (which latter are connected with each other by proper openings) in which fans are mounted, and from which, as well as the holler, cylinder, and parts in connection therewith, common air has been extracted either through displacement or by an air pump. The steam, when allowed to bear on these fans, owing to their position, will drive them round

at a very great speed; but in accordance with the power of the steam, and there being a sufficiency of the above, the steam will, in its progress, lose its power until it has none, or, in other words, be received into a vacuum. These chambers, by their proper ducts, will receive the condensed steam, from which, or other suitable place, it may be pumped back to the boiler, thus forming a continuous revolution of the motive power.—Patent abandoned.

8308 F. A. BLANCHON, Paris. Tops. Dated October 29

3:308 F. A. BLANCHON, Paris. Tops. Dated October 29-1863.

This consists in making use, as a motor for driving tops, of a current of air, obtained by mere insufflation with the human mouth or by suction, and which current is caused to pass through the top, and through suitable re-acting or exit openings provided in the periphery, the current of air imparting rotary motion to the top by its re-acting effect, in a manner analogous to that of the steam in the apparatus called the collepte. The current of air is produced, by preference, by insufflating with the mouth into a tube, situated in or applied to the axial part of the top, suitable openings provided in the periphery of this latter, allowing the exit of the insufflated ur, which, in re-acting on the said exit openings, will impure that top may form either an adhering part of this latter or a separate part, and the same is adapted in an opening provided in the centre of the upper part of the top. Musical or other suitable sounds may be emitted by providing the top with suitable metal tongues or vibrating reeds, or other suitable sonorous parts, and allowing a portion of the insufflated air to act on these sonorous parts.—Patent completed. completed.

completed.

3309 W. H. Liddell, Edinburgh. Treating pig skins.
Dated October 29, 1868.

The inventor first selects the pig skins according to the purposes for which their general qualities render them most suitable; he then cuts and extends them in a contrary way to anything hitherto practised. For long straps the skins are out the longest way, out of the most proper thickness of the skin, and then the other parts of the skin can be economically used in making leggings, bags, and bandages. The bandages hitherto generally used are mule of hard and impervious leather; while the pig skin bandage, according to this method of treating, will be found firm and of a porous nature, admitting of free perspiration.—Patent completed.

3310 R and I WHYTE Glassow. Looms. Deted Octo.

3310 R. and J. WHYTE, Glasgow. Looms. Dated Octo-

3310 R. and J. Whyte, Glasgow. Looms. Dated October 29, 1868.

This relates to avrangements of mechanism for actuating the set or sets of compound or multiple shuttle boxes of looms for weaving striped, checked, and other ornamental or figure fabrics requiring two, three, ormore shuttle boxes and shuttle in each set. The invention consists, first, in the construction and arrangements of the parts of pattern mechanism, and shuttle box, moving and holding mechanism generally, for actuating the shuttle boxes of power looms. Second, in the construction and use of duplex pressers for actuating a lever connected to the shuttle box of a power loom, so as to shift and set or bring these to rest by a positive motion, taken or derived from one of its main shafts, whether the lateral acting position of the depressers is determined by simply bringing it to rest on the pattern pins in the improved manner herein distinguished, or by the positive motion of the pins in turning the barrel. Third, in the construction and use of a reversing pattern barrel with many annular rows of pattern pin holes, having a setting or pattern lever traversed across these holes intermittently by pins in the barrel, for regulating or setting the actual moving mechanism of power loom shuttle boxes, whether the pattern pins used actually move the pattern or setting lever or only form a rest therefor. Fourth, in the construction and use of pattern barrels with simple resting pins only, for determining the position of the pattern lever and depressers of the actual shuttle box moving mechanism of power looms.—Patent completed.

3311 W. Scott, Leeds. Cleansing seol. Dated October 29, 1868.

3311 W. Scott, Leeds. Cleansing wool. Dated Octo-

3311 W. Scott, Leeds. Cleansing secol. Dated October 29, 1868.

This relates to means of drying and cleansing wool or other fibrous substances after any of the ordinary processes of washing such wool or other fibrous substances. A swift or spiked drum of either cylindrical or polygonal form, capable of revolving in conjunction with a spiked roller within an enclosed chamber or framework casing, is employed, such chamber having a door to open and close for the introduction of the wool or other fibre to be operated upon, and the bottom part grated or perforated to allow the dirt or extraneous matters to pass through. The bottom part is circular, and only of suitable radius for the spikes of the swift to run clear of it. The upper part is also (by preference) circular, but raised sufficiently high to clear and leave a suitable amount of space above the spiked roller which revolves above and in near contact with the swift.—Patent abandoned.

tact with the swift.—Patent abandoned.

3312 J. and W. ADAMS, Islington. Bricks and tiles.
Dated October 29, 1868.

This consists in treating or preparing clay, loam, or brick eirth, by adding thereto, and mixing therewith, street or road sweepings, road scrapings, street slop or drifts, chalk and sand, or waste from stone sawing, commonly known as stone sand, or stone crushed, for the manufacture of bricks and tiles, whereby the patentees are enabled to dispense with ashes; also, at the same time, improve the texture, colour, and quality of the said articles, and produce superior bricks and tiles from inferior clay. The number and quantities of the mixing materials above mentioned must be varied according to the colour required and the quality of the materials. The drift and sand, or that whole of the materials being mixed together and added to the clay or loam as the case may require.—Patent completed. completed.

completed.

3313 J. HEATON, Langley Mills. Iron and steel. Dated October 29, 1863.

This consists, first, in the employment of the cinder or slag obtained in the production of steel, or of steely iron, or of iron from products which have been obtained by the action of nitrate of sods or of nitrate of potash upon cast iron, either in a converting vessel or apparatus, such as is described in the specifications of letters patent granted, Nos. 793 and 1867, and No. 1295 of 1866, or in any other suitable furnace or apparatus. Second, in the employment of the product obtained by heating together oxide of iron and carbonate of sods or potash, or caustic sods

potash, or mixtures of the same for the productions of malleable iron or steel from cast iron in what is known as the puddling process, and also its employment in the blast furnace for the purpose of improving the quality of cast or pig iron to be produced. The proportions in which such cinder or slag is employed will depend upon the impurities existing in the cast iron or iron ore, but it is found that when the cinder or slag herein referred to is employed in the proportion of about 14th, to every charge of about 4cwt, of cast iron, and in about the same relative proportions when employed in the blast furnace, that good results are obtained.—Patent completed.

3314 H. WALLWORK, Manchester. Taps or valves. Dated October 29, 1863.

3314 H. WALLWORK, Manchester. Taps or valves. Dated October 29, 1863.

This relates principally to self-closing valves or taps suitable more particularly for water, beer, oil and oth riquids, and consists in the construction, arrangement, and combination of the parts. The valve is a lifting valve, and closes by the pressure of the liquid. The stem part which guides its movement is formed with grooves or channels in the ordinary manner, or it is made tubular, and holes are formed laterally in its upper part to allow the fluid to pass into and through the hollow stem. The seating of the valve is flat, and the facing of the valve (corresponding to the cone part of the ordinary valve) is formed by a ring of india-rubber, leather or other suitable material. The head of the valve is coned. It is lifted when opened by the end of a lever handle acting against the end of the stem of the valve, this lever handle passing through a cylindrical or cone plug fitting a hole formed in the body part of the tap. In using this improved tap or valve, as above described, the lever handle will have to be held so as to keep the valve open so long as the fluid is required to flow, as, when the handle ceases to be held, the valve is closed by the pressure of the fluid. To prevent any damage from the sudden shutting of the valve, an air vessel, having an india-rubber or other suitable elastic diaphragm at its upper end, is backed by an india-rubber or other spring, and arranged so that the orifice for the average pressure of the fluid for which the valve is used, greater the pressure and smaller the orifice in proportion.—Patent completed.

3315 R. Oxland, Plymouth. Extracting tin. Dated Oc-

3315 R. OXLAND, Plymouth. Extracting tin. Dated Oc-

Patent completed.

3315 R. Oxland, Plymouth. Extracting tim. Dated October 29, 1868.

This consists in the employment of grinding apparatus. First, for reducing raw ores of tin to fine powder after they have been partially pulverized by stamps or by a crusher; and, second, for grinding burnt or calcined ores in such a manner as to rub off the adhering oxide of fron and other impurities from the binoxide of tin, or black tin of the Cornish miner, without pulverizing the black tin more than can possibly be avoided. A mill is preferand 2ft deep, provided with a hollow central cone, rising from the bottom to the same height as the upper edge of the pan. Through this cone is a perpendicular shaft, which carries a runner supporting a muller, on which are fastened iron plates or shoes forming the upper grinding surface, which moves over a bed of cast-iron plates fastened to the bottom of the pan. The shoes of the muller are twelve in number, leaving inch radial spaces or channels between each plate. If the ore be ground in charges, these spaces are left open, but if ground in a continuous stream of supply of ore and exit they are filled up with hard wood on end grain to the grinding surface. The about an inch wide on the top, extending three-fourths of the width, so beveiled from the bottom upwards that the end grain wood, with which the channels are filled up, may be held firmly down. Each plate is sufficiently wide to fill up the bottom of the pan, excepting a space of 4in, but were the inner edge and the central cone, and a space, leaving a channel 2in, wide between the the outer edge and the interior of the pan. Between each of the four plates a space an inch wide is left, which is also filled up with hard wood, presenting the end grain to the grinding surfaces. At equal distances on the inside of the pan are slots or channels, for holding three curved pieces of iron, so fixed as to cause the throwing of the pulp from the circumference to the centre when the ore is ground, by running it in a stream of water into t

### APPLICATIONS FOR LETTERS PATENT

Dated May 4, 1869.

1862 W. Seed, Preston, Lancashire. Improvements in furnaces for steam boilers and other purposes.

1863 E. and E. Thomas, Meifod, Montgomeryshire, and J. Morris, Weishpool, Montgomeryshire. A new or improved agricultural implement for forming the surface of the ground into complete ridges, and at the same time depositing manure and sowing seed therein.

1864 O. Topham, Coleman-street, Bunhill-row, Middlesex. Improvements in machines for mincing meat, vegetables, and other similar substances requiring to be minutely divided.

1865 R. Wappenstein, Manchester.

minutely divided.

1365 R. Wappenstein, Manchester. Improved system and apparatus for registering the numbers of passengers travelling in or on omnibuses and other conveyances, or entering public gardens and buildings.

1366 T. Cockroft, Bridge-lanes, Hebden Bridge, Yorkshire. Improved means and method of hanging window

sashes.

1367 J. Bullough, Accrington, Lancashire. Improvements in warping or beaming machines.

1368 R. Fennelly, Wellington Chambers, London Bridge.
Surrey. Improvements in cases for the conveyance of

fresh meat.

1369 T. Perkins, Hitchin, Hertfordshire. Improvements in reaping and mowing machines.

1370 W. E. Gedge, Wellington-street, Strand. An autodynamic carbonic acid gas apparatus for raising liquids and for the preservation of beer.

1371 A. and E. Fau, Castres, Department of the Tara, France. An improved process for washing, freeing from burs, and hairing skins.
1372 J. Tail, Falstaffyard, Southwark, and A. Williams, Great George-atreet, Westminster. An improved method of, and apparatus for bending, curving, straightening, and flattening metallic sheets, plates, or bands, and also round, flat, square, angular and other bars of iron or other metals.

1373 A. V. Newton, Chancery-lane. Improvements in railway carriage wheels.

1373 A. V. Newton, Chancery-lane. Improvements in engines to be used as motors or as pumps for raising or forcing liquid or aeriform bodies.

1375 C. F. Franklin, Abingdon-street, Westminster, and E. Dubois, Primrose-streat, Bishopsgate. Improvements in accommend.

nts in gas engines.

Dated May 5, 1869.
1376 T. Sibley, Ashton-under-Lyne. Improvements in

Dated May 5, 1869.

1376 T. Sibley, Ashton-under-Lyne. Improvements in velocipedes.

1377 D. Adamson, Newton Moor Iron Works, near Hyde, Chester. Certain improvements in portable and other steam engines and boilers, and in apparatus employed in the construction thereof.

1378 J. F. Kent, Thornton Heath, Surrey. An improved mortsing, tenoning, and sawing machine.

1379 G. Clark, Northumberland-street, Strand. Improvements in cartridges and appliances for their construction, manufacture, and use.

1380 W. MacKean, Paisley. Improvements in the manufacture of cattle food.

1781 E. H. Richmond, King William-street, City. Improved apparatus and process for preserving fresh meat and other animal food, fish, poultry, and game, and also ingredients, matters, or substances to be used in combination with the said apparatus.

1382 A. Cocke, Water-lane, City. Improvements in apparatus for ventilating railway and other carriages, which improvements are also applicable to ventilating apartments and other places, and to creating draft is chimneys.

1383 H. Highton, Sussex-square, Brighton, Sussex. Improvements in making, hardening, and preserving artificial stone, and in preserving the surfaces of wells and other surfaces.

1386 C. Moore, Sketty, near Swanses, Glamorganshira. An improved screw propeller for ships.

1385 J. E. Phillips, Grantham, Lincolnshire. Improve-

valves for steam engines.
1386 J. E. Phillips, Grantham, Lincolnshire. Improvements in sewing machines, and in tables for the same parts of which improvements are applicable to other ma-chinery.

chinery.

1387 R. H. Ray, Walden Hall, Saffron Walden, Essex.
Improvements in the construction and arrangements of
reaping and mowing machines.

1388 T. Welton, Grafton-street, Fitzroy-square, Middlesex. A new method of applying oxygenated and other
gas-charged charcoal for curative and other purposes.

gas-charged charcosi for curative and other purposes.

Dated May 6, 1869.

1889 E. N. Hudson, Percy-terrace, Bayswater, Middlesex. Improvements in carriages, vehicles, or conveyances propelled or moved by the power of persons carried or conveyed thereby.

1390 H. E. Newton, Chancery-lane. Improved apparatus for enlarging and reducing basso-relievos, plans or drawings, and writings.

1391 C. D. Abel, Southampton-buildings, Chancery-lane, Improvements in the treatment of cast iron for the production of wrought iron and steel therefrom.

1392 J. Tolson, Dalton, near Huddersfield. An improvement in, or applicable to, certain apparatus employed for cleaning the cards of carding engines or machines having cylinders or rollers clothed with cards.

1393 W. Bennett, Aston, near Birmingham, and J. Currall, Birmingham. Improvements in kitchen ranges.

1394 I. and G. Battinson and T. Whitehead, Halifax. Improvements in machinery for combing wool and other fibres.

fibres.

1895 W. Galloway, Craigie, Ayrabire. Improvements in apparatus for brakeing or retarding railway trains.

1896 W. Galloway, Craigie, Ayrabire. Improvements in apparatus for communicating between passengers, enginemen, and guards in railway trains.

1897 J. Needham, Chiawick, Middlesex. Improvements in velocipedes.

1898 G. Kent, High Holborn. An improved refrigerator.

1398 G. Aen, flight Lordon.

1399 J. M. Hart, Cheapside, City. Improvements in the construction of safes or depositories for security, strong rooms, and such like places; also in fireprooting the same, part of which improvements is also applicable to the construction of parts of locks.

1400 G. T. Bousfield, Loughborough Park, Brixton, Surrey. Improvements in suspenders of braces.

Dated May 7, 1869. 1401 E. Seyd, Princes-street, City. Improvements in

flui fluid meters. 1402 R. Fennelly, Wellington Chambers, London Bridge, Southwark. Improvements in apparatus for washing out

cases. 1403 D. and A. Posener, Mansell-street, Goodman's Fields, Middlesex. Improvements in pipes for smoking

1404 G. N. Mansfield, Great Portland-street, Middlesex.

An improved manufacture of parquet flooring.

1405 J. Ramsbottom, Leeds, and T. M. Pearce, Bradford.
Improvements in steam and hydraulic apparatus for pumping, forcing, and measuring water, and for raising

weights.

1406 A. J. Murray, Albany-road, Camberwell, Surrey,
Improvements in reaping and mowing machines, parts of
which improvements are applicable to other machines.

1407 F. Leonardt and H. Hewitt, Birmingham. Improve-

140? F. Leonard and H. Hewit, Birminguam. Improve-ments in metallic pens, penholders, and metallic boxes for holding pens and other small articles. 1408 J. G. Tongue, Southampton-buildings, Chancery-lane. Improvements in machinery or apparatus for the manufacture of envelopes.

Dated May 8, 1869. 1409 F. C. Knowles, Lovell Hill, Berks.

purifying and converting cast iron into malleable iron or into steel, and for the making and use of materials and appliances for the same.

1410 W. Henderson, Glasgow. Improvements in appartus for finishing woven fabrics.
1411 B. Hunt, Serle-street, Lincoln's Inn. Improve-

ments in horse collars.

1412 H. Myers, Miles Platting, Manchester. Certain improvements in the furnaces of locomotive and other believes.

improvements in the furnaces of locomotive and other boilers.

1413 E. Maybury, G. Matthews, and E. Marston, Pendleton, Lancashire. Improvements in puddling furnaces.

1414 R. and G. Cadbury, Birmingham, and J. M. Rendall, Torquay, Devonshire. A new or improved description of biscuit manufactured from the cacao bean.

1415 E. S. Copeman, Upper King-street, Norwick. An improved method of, and apparatus for, communicating between the several parts of railway trains.

Dated May 10, 1869.

1416 A. B. Hawes, India Office, Whitehall, Westminster.
Improvements in bottles and flasks; also applicable to jars and other vessels.

1417 W. N. Nicholson, Trent Iron Works, Newark, Nottinghamshire, Improvements in hay-making machines.

Nottinghamshire, Improvements in hay-making machines.

1418 H. R. Lumley, Marlborough-place, St. John's Wood. The treatment of molten iron in order to free it from all impurities.

1419 H. A. Dufrene, Rue de la Fidélité, Paris. Improvements in desiccating and preserving meat and other organic substances.

1420 E. Field, Chandos Chambers, Adelphi, Westminster. Improvements in steam fire engines and other pumping apparatus.

1421 C. Lauth, Paris, Rue de Fleurus. Improvements in dyeing and printing.

1422 R. Blezard, Liverpool. Improvements in apparatus for dressing millstones.

1423 W. Currie, Edinburgh. Improvements in the manufacture of cushions, seats, mattresses, life preservers, and other articles requiring to be stuffed.

1424 M. S. Wolfgang, Fairfield, Stratford-le-Bow, Middle-Bex. Improvements in cricket and other balls.

1425 R. F. Hoppe, Cheapside, City. Improvements applicable to musical boxes, albums, and other similar articles.

1426 W. E. Newton, Chancery-lane. An improved process and composition for hardening common control of the process.

articles.

1426 W. E. Newton, Chancery-lane. An improved process and composition for hardening common or grey cast iron, and for converting articles of iron into steel, or imparting thereto a steely character.

1427 W. E. Newton, Chancery-lane. Improvements in

gun locks.

1428 W. B. Smith, Coventry, Warwickshire. Improvements in the construction of watches, chronometers, and other timekeepers. 1429 J. Withers, Handsworth, Staffordshire. Improve-

other timekeepers.

1429 J. Withers, Handsworth, Staffordshire. Improvements in water meters.

1430 W. R. Lake, Southampton-buildings, Chancerylane. Improvements in bronze ordnance.

1431 H. Bessemer, Queen-street-place, Cannon-street, City. Improvements in the manufacture of malleable iron and steel, and in furnaces and apparatus employed for their fusion and treatment.

1432 H. Bessemer, Queen-street-place, Cannon-street, City. Improvements in the construction and mode of working furnaces, and apparatus employed in fusing malleable or wrought iron and steel and pig or other carburets of iron, and obtaining cast steel or homogeneous malleable iron therefrom.

1433 H. Bessemer, Queen-street-place, Cannon-street, City. Improvements in the conversion of fluid crude iron and molten pig or other carburets of iron into fluid homogeneous malleable iron and steel, whether such pig or other crude iron is used alone, or is mixed with a portion of malleable or more or less decarburized iron in a solid or fluid state.

or fluid state.

1434 H. Bessemer, Queen-street-place, Cannon-street, City. Improvements in the treatment of crude or pig iron and other carburets of iron, and in the apparatus employed for such purposes.

1435 H. Bessemer, Queen-street-place, Cannon-street, City. Improvements in the construction and mode of working blast furnaces employed for smelting the ores of iron, and in the mode of employing and utilizing the gaseous products of such furnaces, and also in the construction and mode of working blast engines employed to force air into blast and other furnaces.

NOTICE.—Having received communications from persons NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office MoneyOrder should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

Science and Art.—A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brooches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[ADVT.] SCIENCE AND ART .- A striking instance of the

Butt and Bib Cocks in Iron, with Patent White Metal Plugs, very cheap and durable.

Double Pump in Cast Iron Frame.

# PHILLIPS'S PATENT SOLID FLANGE

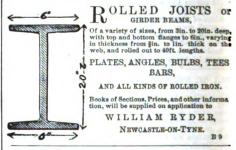

PHILLIPS'S PATENT SOLID FLANGE
GIRDERS give double the strength of ordinary riveted
plate girders of corresponding sectional area and weight, and are
supplied in the usual sections at a lower rate per ton.
Particulars furnished on application to the patentees, W. and T
Phillips, 25. Coal Exchange, E.C.
PHILLIPS'S PATENT IMPROVED FIRE-PROOF FLOORING
dispenses with the use of all Wooden Fillets and Laths; can be laid
by any labourer, and the ceiling plastered immediately; is light and
indestructible, and in combination with the Iron Joista, forms a perfect structure at a trifling cost over the ordinary combustible Timber
Floors.
W. and T Phillips Patentee at Court

Floors.

W. and T. Phillips, Patentees, 25, Coal Exchange, E.C.

PHILLIPS'S ROLLED WROUGHT-IRON JOISTS AND BEAMS
are specially manufactured from a tough and elastic Metal, and
are supplied at the cost of the inferior descriptions of iron in the
market.

W. and T. Phillips, 25, Coal Exchange, E.C.

# COCKER BROTHERS

OCKER BROTHERS

(Successors to Samuel Cocker and Son),
SHEFFIELD.
ESTABLISHED 1759.

MANUFACTURERS OF STEEL FILES AND WIRE: Als of
"COCKER'S" PATENT STEEL ROPE WIRE
In long lengths, from 10th to 40th, becees, without welding, and espable of bearing as high a breaking strain as any in themarket. Each
pable of bearing as high a breaking strain as any in themarket. Each
piece warranted to twist round its own diameter.
Three First-Class PRIZE MEDALS were awarded to SAMUEL
COCKER and SON, Sheffield, at the Great Exhibition of Industry,
London, 1831.
First-class PRIZE MEDAL was awarded to COCKER BROTHERS
at the Universal Exhibition of Industry, Paris, 1835, and MEDAL of
HONOUR awarded to COCKER BROTHERS, by the Society of Arts
and Industry, London, 1836.

MOULTON'S PATENT EMBEDDED

STEEL AND INDIA-RUBBER SPRINGS for Railway Carriages, Locomotive Engines, Buffers, &c., possess greatly-increased power, as compared with the ordinary India-rubber Springs; are more uniform in their action, counteract the compressibility of India-rubber alone, and are not liable to break from sudden concussion, or the inequalities of the permanent way.

Prices and further particulars may be had on application to the Patentees, & MOULTON & CO., Maunifacturers of India-rubber Springs, Steam Facking, Washers, Hose, Tubing, Machine Belting, Garmanta Blankets, Sheeting, Elastie Hot Water Beds, Cushons, &c., &c.

Kingston India-rubber Mills, Bradford, Wilts.

UXURIANT WHISKERS, of HAIR-A retired apothecary, from Wales, will send his noted FORMULA for 13 stamps and stamp-directed envelope, to produce Hair on the Head, Whiskers and Moustaches on the Face in three weeks.—MR. EVAN EVANS, M.D., C.M., DORKING, Surrey.

LADIES and GENTLEMEN, having a connection, may hear of an AGENCY that will add to their income from £3 to £5 per month. Address (enclosing stamped envelope), JAMES JEFFERSON, Esq., Forest Hill, London, S.E.

LONDON: FRIDAY, MAY 21, 1869.

### THE CAPTIVE BALLOON.

SIX months since we penned some remarks upon the interesting features which presented themselves to the scientific mind when up in a balloon.\* We then observed that in a very short space of time anyone who had not been up in a balloon would be regarded as one behind his time, and would regarded as one behind his time, and would be placed in the same category as those who had never ridden in a Hansom cab, nor travelled on a railway. The time to which we then looked forward has arrived, and it is now open to any one who likes to take boat, 'bus, or rail to Chelsea, to make an ascent in one of the finest and best appointed balloons that ever floated in the air. This splendid aerostat is the property of M. Giffard, the inventor of the well-known injector, and by whom it was constructed. It is now on view in the Ashburnham Park, Chelsea, where it is daily making captive ascents—weather permitting. In one of these ascents we had the pleasure of joining yesterday week, on the invitation of the proprietor, and which ascent we briefly recorded in our last number. On that occasion, Mr. Glaisher made the ascent with the view of taking some meteorological observations near the earth, which the gradual ascent of a captive balloon would permit of, and which he had not been able to take in a free balloon, owing to the rapidity with which it always left the earth. On that occasion, too, there were present Lord Richard Grosvenor and Lord Dufferin, members of the council of the Aeronautical Society of Great Britain, Mr. Brearey (the secretary), Mr. T. Cargill, C.E., and several other scientific gentlemen. But the elements were unpropitious; a stiff breeze suddenly sprang up, which obliged the party to return to earth after an altitude of about 2,000ft. had been reached. The circumstance, however, served to show how perfect all the arrangements were, and how thoroughly under control the immense machine was. As we made the ascent shortly before going to press, we had not time to place the details of the apparatus before our readers; we, however, propose to do so now.

Those who visited Paris during the last Great Exhibition will, doubtless, remember M. Giffard's captive balloon, and the machinery by which the ascents and descents were regulated. This machinery has now been brought to London, together with a balloon 23ft. larger in diameter than the Paris balloon, and a rope of much greater length. On entering the Ashburnham Park, the visitor finds himself in a circus 246ft. in the visitor finds himself in a circus 246ft. in diameter, encircled by a screen of timber framing, 80ft. in height, and covered with canvas. In the centre of this arena is a well about 15ft. deep, over which the balloon, when not on a journey, is held in place by numerous guy ropes. This balloon is 93ft. in diameter, and when inflated contains 421,161 cubic feet of gas, pure hydrogen being the gas used. The material of which the balloon is constructed is composed of one layer of linen interior, united to another the balloon is constructed is composed of one layer of linen interior, united to another layer of the same material, by means of a solution of india-rubber. Outside this is a layer of Cretonne linen, the attachment being formed by a vulcanized india-rubber composition. The exterior is finished with two coats of gum shellac varnish, over which again are laid fine coats of boiled linseed oil. From the balloon is suspended a circular car, having the centre open for the passage of the rope, which is attached directly to the body of the balloon. The car will accommodate about twenty-five persons; this was, in fact,

the number that made the ascent to which we have referred. The rope is made fast to a pressure gauge, having a horizontal dial, upon which a pointer indicates the strain put upon the rope at any moment. The balloon weighs 6,000lb.; the core netting, with which it is covered, and the necessary guy ropes, &c., which are very numerous, are stated to weigh 4,000lb.

The main rope by which the balloon is held captive, weighs 4,350lb., is 2,150ft in length, and is 23in. in diameter at the end next the balloon, gradually tapering to 2in. diameter at the end next the winding drum. The object of thus tapering the rope, is that its weakest part may be nearest the ground, at which point it would first give way, if it broke at all—which is hardly probable. By this means, if such an event did take place, there would be no danger to those below, from a heavy mass of rope falling upon them. It would also act somewhat as a brake upon the balloon, which would otherwise shoot upwards at a terrific rate, when suddenly relieved of its load. The rope passes from the balloon over a pulley wheel 5ft. 6in. in diameter, which is so arranged that it allows the rope to pass freely over it, no matter what angle it may take. It is, in fact, swivelled horizontally and vertically, and has a heavy counterbalance weight attached to it. This pulley wheel is held down by a strong framework, which is built into the earth, and is weighted with 50 tons of brick iron and timberwork. which is built into the earth, and is weighted with 50 tons of brick, iron, and timberwork. The rope passes horizontally from the pulley along a gradually widening tunnel to the winding drum which is placed at the far side of the circus. This drum is 23ft in length and 7ft. in diameter. It is cast in lengths, and is grooved to receive the rope. The drum is is grooved to receive the rope. The drum is surrounded by a platform, at each end of which is a double-cylinder steam engine of horizontal construction. These engines drive the drum by means of toothed gearing; they receive steam from two vertical boilers placed in the rear of the circus. The boilers are of French construction, by M. Duresnes, as are also the engines, which are by M. H. Flaud. The winding drum was made in London by M. Babeaud, the engineer in charge of the balloon machinery.

On a piece of spare ground in the rear of the circus is the apparatus for producing the gas. This consists of a series of wooden vats in which scrap iron is placed in a solution of sulphuric acid. The gas is drawn off to a receiver, and is made to pass through a washer and a purifier, after which it is stored in a gas holder ready for use. The balloon is always kept inflated, but there is always a loss going on from condensation, the deficiency being made good every evening. The cost of the balloon and apparatus has been something considerable, as will be seen from the following items:
—Cost of balloon, £2,000; netting, guy, and
other necessary ropes, £2,000; main holding
rope, £220; engines, boilers, and machinery to work the balloon, £4,000; gas works, £1,200. These items—which are not all that could be enumerated—represent the respectable sum of £9,420, and when we add that the gas for one inflation costs £600, it will be seen that M. Giffard has made an investment of no light nature, but which we trust will prove as satisfactory to himself as his balloon will prove attractive to the public. A careful examination of the whole apparatus has satisexamination of the whole apparatus has satisfied us that everything is as safe as human ingenuity and foresight can make it. Two experienced aeronauts, MM. Godard and Aymo, accompany each ascent, whilst the manager is M. Yon, who manufactured the whole of the ropes and netting, and also constructed the balloon for M. Giffard. We can but wish success to this novel enterprise, which we are sure will be well patronized by

THE MARTINI-HENRY RIFLE.

RUMOURS of a peculiar character are at present rife as to the intentions of the Government with respect to the Martini-Henry rifle. This is especially the case on the Continent, where the idea prevails, in some quarters, that the Government are now hesitating about the adoption of this rifle as the service arm, and may possibly, after all, abandon it altogether. There is no positive foundation for such a supposition, and the only negative one we can discover is that the Estimates did not include extravagant votes for this arm. It may, therefore, be as well briefly to place before our readers the present position of matters, which we are enabled to do from personal observation and knowledge of the circumstances. The hands at the Government works at Enfield are now engaged in finishing the last order for 35,000 Snider rifles, which order will be completed by September next. These arms are required for the service, and their completion will use up a quantity of material already prepared for them. When these rifles are out of hand, the manufacture of the Martini-Henry gun will be commenced, and be proceeded with until a sufficient number are turned out to enable the arm to have a fair practical trial. After this has been made, and the arm reported to be satisfactory, the manufacture will be con-tinued at the Government works, besides which, contracts will be entered into with private manufacturers to supply the weapon. The machinery at Enfield will require very The machinery at Enfield will require very little alteration, and, besides cutters and other tools, there will scarcely be any new machinery. By the end of the year the officials at Enfield expect to be turning out about a thousand rifles per week. Such is the present position of our future military arm, and we trust this simple statement may allay the hopes and fears which we have heard expressed of late both at home and abroad.

# ELECTRICAL BALANCE THERMOME-TER FOR MEASURING TEMPERA-TURE OF DEEP SEA.

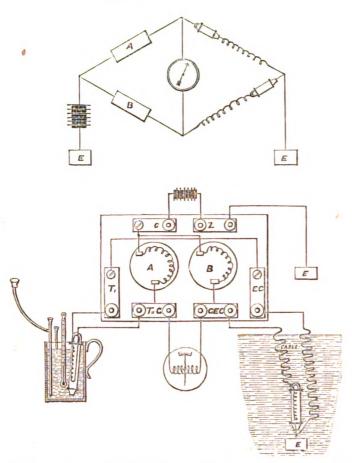

NHE system of measuring temperature by variation in the resistance of metals to the passage of the electric current arising from changes in temperature was first applied by Mr. C. W. Siemens, F.R.S., in 1860, during the manufacture of the Malta and Alexandria Government cable at Greenwich. A certain portion of the cable in one of the tanks was found to give results of insulation and resistance of the copper conductor that could be only due to a far higher state of temperature than was apparent by the thermometer. On a careful examination, it was found that a large amount of the coil exhibited symptoms of spontaneous heating. It is not our intention to refer to the causes which produced this effect, but simply to show how the variations in the resistance of the copper conductor enabled this extra heat to be at once observed. In order to avoid the recurrence of this spontaneous heating in the coil, certain instruments, which may be termed "resistance thermometers," based upon the principle that the resistance of copper wire varies in a constant ratio with the temperature, were constructed and placed at regular intervals between the coils. These at regular intervals between the coils. instruments consisted of several layers of insulated wire of a known resistance (at a standard temperature), protected by an iron core. By connecting any of these "thermometers" with the testing apparatus, any variation in their resistance, as compared with the original standard, would immediately denote a change of temperature, and the temperature itself, calculated from known the public, whenever the weather will permit temperature itself, calculated from known of ascents being made. There is now no excuse for the public not enjoying the privilege of a balloon ascent, which luxury has hitherto only been allowed to a select few.

#### THERMOMETER. BALANCE ELECTRICAL

BY MR. C. W. SIEMENS.

fitted out for deep sea soundings, and the general want of success attending the experiments relative to the determination of the sea temperature at extreme depths, have caused Mr. Siemens' attention to be brought to the subject, and he has so far improved the original "resistance thermometer" for this special purpose as to make it now one of our most valuable assistants in penetrating the hidden mysteries of the deep sea.

At the late soirée of the Royal Society, the improved form of "balance thermometer" was exhibited, and obtained a large share of attention. A set of similar apparatus has been supplied to Dr. Carpenter, who proceeds (in the "Porcupine") on a surveying expedition in the North Atlantic. The apparatus tion in the North Atlantic. The apparatu altogether consists of the following parts, the resistance thermometer and sounding line to which it is attached, and electrical bridge and balance thermometer. The resistance thermometer consists of a coil of fine iron wire, silk covered, of a total resistance of 500 B.A. units. This is contained in an inner tube of metal, the whole of which is dipped into melted paraffin wax, so that per-fect insulation is obtained. The inner tube containing the "resistance wire" is enclosed in an outer tube, perforated with holes, so as to allow the free passage of water. The sounding line is, of course, any length required; and it may be remarked that the maximum length is all that is required. No cutting or shifting for shorter lengths. The cutting or shifting for shorter lengths. facility of using the line for a cast in 100 fathoms for 1,000 fathoms is the same. This line contains two gutta-percha insulated copper wires of equal length and resistance, served with the best hemp, and sheathed externally with copper bands; so that the line—of no great thickness, but great strength -presents a smooth and even exterior. One of these wires terminates at the bottom, and is connected on to the outside of the line, a good connection being made round the copper. The second wire is connected to one end of

the "resistance thermometer," the other or lower end of which is brought out and connected to the copper sheathing at the same point that the first line is connected to. The reason of this will be shown directly.

The electrical bridge and balance thermometer are the instruments used on board the vessel to measure the temperature indicated by the "resistance thermometer," just described. The bridge is that known as Wheatstone's bridge, or parallelogram, and is the favourite electrical instrument in use for the measurement of resistances. upper figure shows the theoretical arrangement. The battery is connected at one end to the arms A B, and the electric current divides and passes through the two arms, and through the two arms at the opposite extremities to earth (E). Exactly in the middle, joining these arms together, is a galvanometer. At the points A and B are placed two equal resistances, or two resistances bearing a known ratio to each other. In the two other arms are placed—in one, a set of standard resistances; and in the other, the resistance to be measured. So long as the resistances in the arms bear the same ratio to each other, the tensions of the battery at galvanometer connections are equal, and no deflection is observed in the galvanometer; the same ratio, then the galvanometer; the same ratio, then the galvanometer is deflected to one side or the other. When the resistances A and B are equal, and the resistance in the third arm is altered until no current passes through the galvanometer. current passes through the galvanometer, then we know that the resistance thus altered is exactly equal to the fourth arm.

The system in this special bridge for the resistance thermometer is the same in principle, but the peculiar difference consists in altering the resistances. The second diagram will explain the connections. The battery is

ances, where the battery current divides equally, one half passing through A, the other through B. The ends of A B pass to the plates  $T_{\rm II}$  and G; at the terminals G G the the plates  $T_{11}$  and G; at the terminals G G the galvanometer is inserted. From G E C the current passes (down the one arm) through one of the wires of the sounding line to the resistance thermometer and to earth on the line; the other half of the current passes (down the other arm) from  $T_{11}$  to a balance thermometer, placed in a specially fitted vessel, provided with two tubes, and immersed in water. After passing through the thermoin water. After passing through the thermometer, the current passes round by the earth connection (E C) to the second wire in the sounding line, and makes earth at the bottom of the line, in the same place that the other thermometer makes its earth connection. These two thermometers are constructed precisely alike, so that if they were placed in the same water, having a perfectly uniform temperature, no deviation of the galvanometer needle would be observed. The modus operandi may be briefly stated. The resistance thermometer, with line attached (the other ends being to their proper connections on the bridge), is dropped overboard. A change of temperature at once takes place; the resistance of the iron, as the water gets cooler, decreases rapidly. On connecting the cooler, decreases rapidly. On connecting the battery by a key to the bridge, the needle is at once deflected, showing the change. An alteration is made in the resistance of the balance thermometer by cooling the water, until the needle is brought to zero; and as alteration occurs after alteration, so the water of the vessel has to be cooled, the object being to keep the needle as near as possible to zero. A delicate thermometer is kept immersed in the water, so that every change, however slight, is noted. The beauty of the balance arrangement is that the variations of temperature throughout the descent of the line can be noted. The tubes in the vessel are—one for admitting the cooling mixture to the bottom, and the other for blowing in, so that the water is at once rendered of a tem-perature quite uniform. The sensitiveness perature quite uniform. The sensitiveness of these thermometers is so great that a variation of one-tenth of a degree Fah. can be observed. The electrical apparatus is so simple, and so devoid of anything requiring arrangement or adjustment, that a perfect novice can manage it. A further improve-ment has just been made to it by the substitution of a small magneto-electric machine, provided with a Siemens' armature. does away with the necessity of looking to the battery, and renders any derangement less unlikely.

It is possible that an objection might be made to the copper sheathed line instead of an ordinary deep sea line; but the copper sheathed line has an advantage over the ordinary line, in giving very little resistance in water. From experiments tried, it will go down to a depth of 2,000 fathoms in threequarters of an hour, instead of about two hours with the old line. In raising the line, the advantage is still more in favour of the copper sheathed line.

The special advantages of this method electrically, are-the excellence of the earth connections, there being no polarization; the effect of the leading wires is entirely eliminated; the ratio of increase of electrical resistance by increase of temperature is rendered immaterial; no calculation is required; where the temperature to be ascertained is higher than that in the vessel containing the "balance thermometer," the process is similar, only warm instead of cold water has to be introduced. Amongst the applications of this instrument may be mentioned its adaptability for medical purposes—it can be made as small as a pencil case
—and for breweries, where the temperature of each vat could be measured from the officeconnected with the plates C and Z, the latter a fact worthy of notice, when it is to be co of which is to earth (E). From C the connection passes to A and B, two equal resist- upon the temperature during fermentation. a fact worthy of notice, when it is to be considered that the quality of beer depends greatly

### THE ROYAL INSTITUTION.

O<sup>N</sup> Thursday, May 6, Professor Tyndall, in his fifth lecture upon "Light," exhibited a magic lantern arrangement, whereby it is possible to throw a very fair spectrum upon a screen. It consisted of a piece of wood, with a vertical slit cut through it, which was inserted in the place of a slide in the lantern, so that, when a bisulphide of carbon prism was placed close in front of the object glass, the image of the slit was de-flected, and transformed into a spectrum. The ordinary oil light, or even a candle, may be used in the lantern, and many experiments may be shown by this arrangement, though the spectra from such sources of light are necessarily always very deficient in chemical rays. Dr. Tyndall next illuminated a tall glass jar of pure water with the electric light, and poured some strong solution of sulphate of quinine in tartaric acid into the liquid, the result being that those who observed the jar by reflected light saw a beautiful blue cloud descending in the water, caused by the lowerextra violet rays in the electric light. In reality, there was no cloud, for to those in the rear of the liquid, who viewed it by transmitted light, the water remained per-fectly transparent. The lecturer explained that the ultra-violet rays in the electric light came more from the non-luminous space between the carbon points than from the intensely luminous points themselves. The distance of the points from each other makes very little difference in the brilliancy of the visible spectrum, but a very considerable difference in the quantity of extra-violet rays thrown upon the screen, as proved by the intensity of the fluorescence exhibited by paper washed in sulphate of quinine, and held in that part of the spectrum. Professor Tyndall also exhibited some experiments to illustrate phosphorescence, which it is believed differs only from fluorescence in the fact that the molecular disturbance set up by light, lasts some little time after the exciting cause is removed.

The lecturer then entered into the principles of spectrum analysis. When the light from a white-hot solid body is spread out as a spectrum, that spectrum is continuous, displaying all the colours of the rainbow, melting gradually into each other. When the light comes from a substance raised to the condition of gas or vapour, bright coloured lines, characteristic of the chemical substance used, fall upon the screen. Lastly, when the light originates with a white-hot mass, surrounded by a vapourous envelope, the continuous spectrum is cut here and there by dark lines, characteristic of the substances forming the vapours. The light of the sun gives a spectrum of the last description, from which fact it is known that the light of the sun originates with white-hot solid or liquid matter, surrounded by an atmosphere of vapours of chemical substances common upon the earth. Professor Tyndall said that from the dark bands of the spectrum we can determine what substances enter into the composition of the solar atmosphere. One One example will illustrate the possibility of this. Let the light from the sun and the light from incandescent sodium vapour pass side by side through the same slit and be decomposed by the same prism. The solar light will produce its spectrum, and the sodium light its yellow band. This yellow band will coincide exactly in position with a characteristic dark band of the solar spectrum, which Fraunhofer dis-tinguishes by the letter D. Were the solar tinguishes by the letter D. Were the solar nucleus absent, and did the vapourous photosphere alone emit light, the dark line D would be a bright one. Its character and position prove it to be the light emitted by This metal, therefore, is contained nosphere of the sun. The result is in the atmosphere of the sun. The result is still more convincing when a metal which gives a numerous series of bright bands finds a lecture upon his system of working artillery,

each of its bands exactly coincident with a dark band of the solar spectrum. By this method, Kirchhoff, to whom we owe, in all its completeness, this splendid generalization, established the existence of iron, calcium, magnesium, sodium, chromium, and other metals in the solar atmosphere; and Mr. Huggins has extended the application of the method to the light of the planets, fixed stars, and nebulæ.

The light reflected from the moon and planets is solar light, and, if unaffected by the planet's atmosphere, the spectrum of the planet would show the same lines as the solar spectrum. The light of the moon shows no other lines. There is no evidence of an atmosphere round the moon. The lines in the spectrum of Jupiter indicate a powerful absorption by the atmosphere of this planet. The atmo-sphere of Jupiter contains some of the gases or vapours present in the earth's atmosphere. Feeble lines, some of them identical with those of Jupiter, occur in the spectrum of Saturn. The lines characterizing the atmospheres of Jupiter and Saturn are not present in the spectrum of Mars. blue portion of the spectrum is mainly the seat of absorption, and this, by giving predominance to the red rays, may be the cause of the red colour of Mars. All the stronger lines of the solar spectrum are found in the spectrum of Venus, but no additional lines. As regards stellar chemistry, the atmo-sphere of the star Aldebaran contains hydro-

gen, sodium, magnesium, calcium, iron. bismuth, tellurium, antimony, mercury. atmosphere of the star Alpha in Orion contains sodium, magnesium, calcium, iron, and bismuth. No star sufficiently bright to give a spectrum has been observed to be without lines. Star differs from star only in the grouping and arrangement of the numerous fine lines by which their spectra are crossed.

The dark absorption lines are strongest in the spectra of yellow and red stars. In white stars the lines, though equally numerous, are very poor and faint. A comparison of the spectra of stars of different colours suggests that the colours of the stars may be due to the action of their atmospheres. Those constituents of the white light of the star on which the lines of absorption fall thickest are subdued, the star being tinted by the residual colour. Turning from the stars to the nebulæ, some nebulæ give spectra of bright bands; others give continuous spectra. The light from the former emanates from intensely heated matter existing in a state of gas. This may in part account for the weakness of the light of these nebulæ. It is probable that two of the constituents of the gaseous nebulæ are hydrogen and nitrogen.

At one time it was possible to examine the At one time it was possible to examine the rose-coloured solar prominences only during an eclipse, but Mr. Janssen in India, and Mr. Lockyer subsequently, but independently, in England, proved that the bright bands of the prominences might be seen without the aid of a total eclipse. By sending the black which the series and eclipse in the light tending the series of the prominences. ing the light, which, under ordinary circumstances, masks the hydrogen bands, through a sufficient number of prisms, it may be dis-persed, and thereby enfeebled in any required degree. When sufficiently enfeebled, the undispersed light of the incandescent hydrogen dominates over that of the continuous spectrum. By going completely round the periphery of the sun, Mr. Lockyer found this hydrogen atmosphere everywhere present, its depth (generally about 5,000 miles), being indicated by the length of its characteristic bright lines. Where the hydrogen ocean is shallow the bright bands are short, where the prominences rise like vast waves above the level of the ocean the bright lines are long. The prominences sometimes reach a height of 70,000 miles. Professor Tyndall closed this interesting lecture by explaining the

by utilizing the force of the recoil of the gun to lower the gun below the parapet for loading, and by means of a counterbalancing weight to raise it again for firing. Thus a large lateral range is commanded, and the large lateral range is commanded, and the necessity for embrasures in the fortifications is avoided. The system has already been described in detail in these columns. On the following day, May 8, Professor Seeley, the reputed author of "Ecce Homo," gave the first of three lectures upon Roman history, and entered fully into the subject of the constitution and addition of the Pompa continuous and the pompa continuous an stitution and condition of the Roman empire in the time of Cæsar. On Tuesday, May 11, as well as on the previous Tuesday, Professor R. Grant, F.R.S., continued his lectures upon stellar astronomy. He explained in detail all the difficulties in the way of measuring the motions and distances of the fixed stars, and how those difficulties have been overcome.

# NOTICES OF BOOKS.

WHEN Mr. Fairbairn gave the profession a second edition of his treatise on iron and steel manufacture, he predicted that great changes would, at no great distance of time, occur in that department of industrial art, and which would result in the production of a superior article. These changes have, to a great extent, occurred, and have necessitated another edition of Mr. Fairbairn's most useful work, which now lies before us.\* The verification of this prediction has been chiefly accomplished by the extension of the Bessemer process, and the gradual introduction of the homogeneous system into the manufacture of metals. Mr. Fairbairn describes all the new improvements, including the Heaton process, which, by the introduction of the crude nitrate of soda, results in the production of "steel-iron" from any kind of pig iron. This method of manufacture is described in a chapter which embodies the improvements in the manufacture of iron and steel from 1864 down to the present time. The work is fully illustrated, and contains some valuable information upon the properties of the materials of which it treats.

During last year, a series of very interesting articles upon the industries of Scotland appeared in the weekly issue of the "Scotsman." These articles were fair and accurate accounts of the various branches of trade, and we are now glad to see them collected together and reproduced in a more permanent form. † The volume in question is a history of the rise, progress, and present condition of the Scottish industries, especially of those which, by their extent or peculiarity, merit notice. Mr. Bremner judiciously confines himself to a plain narrative of facts, which have been carefully selected, and are interspersed with here and there a few general reflections. Iron works, coal mines, shipbuilding establishments, railway works, linen and cotton works, Many scenes of labour are depicted, which are only known to most of our readers by name. In Mr. Bremner's book, our friends will find entertainment and instruction admirably combined, whilst as a book of reference upon the Scottish industries, it will for some time remain an authority.

Weale's rudimentary series continues to receive fresh accessions of useful information. No. 163 of the series is a legal exposition of the patent law,; which conveys reliable information upon this part of the subject. It sets forth the state of the law, resulting from decisions more recent than those ni any other work, and will prove useful in this respect to all engaged in the work of patenting inven-tions. The author has added some explana-

tory notes on the law as to the protection of He effects this by directing the current of

designs and trade marks.

Mr. David Page, who has contributed largely to geological literature, has recently given the science-seeking public yet another boon in his "Chips and Chapters on Geology."\* The present volume is intended for those who, having neither need nor time for a systematic course of study, still wish to make themselves familiar with the more prominent facts and bearings of geology. The author places before his readers a collection of mis-The author cellaneous matter relating to the subject, which he has selected with a view to instruction in the general principles of this science. has so modified and arranged the whole, that we have a very attractive volume, which is alike fitted for the young geologist, as well as for those readers who do not wish to dive deeply into this attractive science.

We have now got half way through Mr.

Bourne's work on modern engines, Parts XI. and XII. being now to hand. In these, as in those which have preceded them, there is no lack of interest. After pointing out the probable course of improvement in locomotives, the author gives a condensed account or recapitulation of the principal classes of improvements in the steam engine, which have been propounded at various times in its history. These are arranged chronologically, dates and the numbers of patents—where patents have been obtained—being given. Thus, independently of the practical observations of the author, we have a very complete index of the subject, which, of itself, will prove of great value to many designers and improvers of steam engines. A large folding plate of Captain Ericsson's original "Monitor," showing the screw and turret machinery, accompanies Part XI., whilst Part XII. has two plates, giving the details of surface-condensing engines, by Messrs. Richardson.

Mr. Burgh's treatise on screw propulsion, which was to have been completed in fifteen parts, has been extended to sixteen. This extension has been decided upon in order that the work may embody some very recent important matter on screw propellers, which has been exclusively given to the author by our leading marine engineers. The author has thus exercised a wise discretion in thus extending his work, and to which none of his readers will object. Parts XIII., XIV. and XV. of this treatise are now before us; they are chapters on a new principle of the screw propeller, by Mr. Arthur Rigg, who has made some very interesting experiments with the screw, the results of which he here embodies. Mr. W. Langdon supplies a chapter on thrust blocks, and Mr. Burgh follows with another on the same subject. In Chapter XX., Mr. Burgh reviews comparatively the whole family of modern screw propellers as constructed by our principal marine engineers. In the succeeding chapter, Mr. Burgh gathers into a focus the opinions and ideas of all the engineers who have contributed to his treatise. In this chapter the last page of Part XV. finds us. The illustrations of these three numbers consist of lifting frames for the screw propeller; the feathering screw of the "Aurora"; and the details of the methods of screw propulsion adopted in various other vessels.

Mr. C. J. Richardson, whose name is intimately associated with the liquid fuel question, has been busying himself of late with the smoke nuisance, and has given us a pamphlet on the subject (Atchley and Co., Great Russell-street). Mr. Richardson proposes the cold water cure for this domestic evil; his remedy is to pass the smoke through a water spray.

smoke over a bridge just beyond which a jet of water acts on it. The soot and water are of water acts on it. carried down another flue to a pipe leading to the outside of the house, and thence to the The idea is certainly an ingenious sewer. one, and has proved effective in experiment. But how about the noxious gases ascending from the sewer, Mr. Richardson?

Mr. J. Conyers Morrell is the patentee of an apparatus for carrying out the dry ash sanitary scheme, of which he is a strong advocate. He read a paper on the subject, two months since, at Manchester, and which he has now published in pamphlet form (Powlson, Bow-street, Manchester). As may be supposed, the author proves that his system is the system for reducing the high death rate. Mr. Morrell states that irrigation cannot as yet claim to be a successful means of disposing of sewage matter, and thus of reducing the high death rate. Mr. Morrell is probably not aware of what Mr. Baldw n Latham has done for Croydon. He has half ruined the under-

Messrs. Cassell, Petter, and Galpin, have just issued two more of their useful primary series of elementary text books. The first of these is on human physiology, and contains one hundred questions for examination. It is written by Mr. Ellis A. Davidson, who has written other works of the same series. The other work is an elementary history of Great Britain, written by the Rev. W. E. Little-wood, M.A. This enterprising firm have also issued the second parts of each of the following of their popular drawing copies:-Series A, floral and vegetable forms; B, model drawing; C, landscape drawing; and D, figure drawing. The studies are well selected, and are calculated to rapidly advance the careful student. Each of these series is to be

completed in twelve parts.

Four pamphlets and a trade price book complete our list of books to the present time. The first of these pamphlets is on fluid resistance to uniform velocity and the relative values of power, form, volume, and velocity, in designing steam and sailing ships; also steam, sailing, and wager boats. It is by Mr. George Sole, N.A. (Trübner), and was written for the purpose of being read as a professional paper in a public institution. Failing this, the author has published it in the hope of its proving of general utility. Its contents are worthy the consideration of naval architects; they tend to prove that the velocity may be known by an estimated calculation as truly as any other engineering matter. The second pamphlet is on London water supply, by Mr. II. H. Fulton (Stanford, Charing Cross). It gives an outline of Mr. Fulton's proposed method of supplying London with water from the source of the river Wye in North Wales. The third pamphlet is on polar magnetism-its astronomical origin, its period of revolution, and the synodical period of the earth identical. It is a lecture delivered by Mr. John A. Parker before the American Geographical and Statistical Society (Trübner). The author distical Society (Trübner). The author disagrees with astronomers on various points, especially upon the subject of the precession of the equinox. Our fourth pamphlet is a contribution to the literature of perpetual motion, by Mr. John C. Gardner (Yates, Chancery-lane), who claims to have practically solved the grand secret. The price-book is that of the Wardour (Chilmark) and Tisbury Stone Company, and, like most books of its class in the present day, it contains some useful hints upon the subject of which it treats.

OTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

PRESERVATION OF MEAT BY COLD.

THE effect of a low temperature in preventing the putrefaction of animal substances is no

historic mammoth was found in Siberia buried in snow, where it must have lain for ages and ages, and yet was fresh enough to furnish food for the dogs that assisted in disinterring it, and even before then, men's mind have been occasionally turned to the preservation of meat by means of cold. But now the preservation of meat in a fresh state becomes every day a matter of greater and greater importance. Our country is unable to afford us sufficient animal food for our population. Our imports of live cattle are necessarily restricted; and, unfortunately, we are too liable to import cattle diseases with cattle. From one cause and the other, our imports have no effect in reducing the price of meat; and the consequence is that our labouring population is greatly underfed, more especially the agricultural part. It is stated, and, no doubt, with truth, that, in many counties, only the heads of families eat meat, and they not oftener than once or twice a week. Under these circumstances, any plan for the importation of fresh meat from distant parts of the world deserves serious consideration. Mr. Julius Jeffreys, F.R.S., has just propounded a plan by which, as he says, under the protection of deep congelation, large cargoes of fresh meat may be imported from Australia and South America, at a cost, exclusive of freight, of about a farthing a pound. The man who really succeeds in doing this will be one of the greatest benefactors of the age, and we sincerely hope that Mr. Jeffreys' plan will succeed. Without attempting to give a description of the somewhat complicated apparatus which the inventor proposes to employ, we may say, in a few words, that the joints of meat, covered with extract of meat to keep out air, are packed in boxes provided with thin metallic sides—that is, a good conducting medium—and these boxes are exposed to a current of air, reduced to a very low temperature by the application of ether spray. In this way, the meat is frozen into a solid block, and in this state is delivered into the hold of the ship, where, by the continued application of cold air, it is kept frozen during the voyage. We do not understand that Mr. Jeffreys' apparatus has been put into actual operation. The theory of the process is perfect and of its success we have not much doubt, but the success requires to be demonstrated; and we hope some of the wealthy men who listened to the explanation of the process will assist the inventor in carrying out his schome.

We have said that we have little doubt of the success of the plan, but there is this much to be said against it. Although it is quite true that meat kept in ice does not undergo actual putrefaction, some incipient changes do undoubtedly take place: the meat loses much of its flavour, and, when it is thawed, it very rapidly begins to putrefy. Mr. Jeffreys proposed to arrive at a temperature considerably below the freezing point of water, and, by this means, he conjectures that he will be able to oppose a solid mechanical obstacle to any movement of molecules, and so prevent the incipient change of which we have spoken. We should add also that it is one peculiarity of his process to thaw the meat very gradually when it is delivered for consumption, and this may prevent the rapid putrefaction which sets up when it is quickly thawed. Everyone who wishes to see our popula-tion well fed and nourished for physical and mental exertion, must desire to see some such plan as this perfected. Preserved meats, as we ordinarily get them, are not—and never will be—popular with the working class, who, as a rule, are more particular about their food (especially skilled artizans) than any other class. The meat must be fresh, and the joints must be well formed; and if such can be supplied from the enormous resources of the Southern hemisphere, now mainly wasted, at a very moderate cost, an immense benefit will be conferred on society, and proportionate profits will accrue to those engaged in the supply.

# PARLIAMENTARY NOTES.

VELOCIPEDES are beginning to occupy the attention of Parliament, for we find Mr. Hambro asking the Postmaster-General last Thursday evening if it was a fact that in certain parts of Wales the post-office mails were now conveyed on velocipedes instead of on horses; and if this change had been found to add to the efficiency and ecorecent discovery in science. Ever since that nomy of the service. The Marquis of Hartington

replied that no such change as that was at present contemplated. The experiment had been made, or would shortly be made, of allowing rural post messengers in certain districts to use those machines on roads which were not very hilly, but as the practice of riding or driving on bicycles had not come under examination by the Civil Service Commissioners, the use of them must, for the present, at least, remain optional.

On the same sitting, Mr. Armistead asked what means those seamen of the mercantile marine who might have claims upon the Greenwich Hospital Fund had adopted to obtain their share of the £4,000 set apart by the Government for their benefit. Mr. Childers said that the allotment of the £4,000 to the seamen of the mercantile marine had only been proposed by the Government in the Greenwich Hospital Bill, and until that measure became law those seamen would have no means of claiming any part of the fund. When the bill passed, the Admiralty would communicate with the Board of Trade for the purpose of seeing that the alterations were properly made.

In answer to a question from Mr. L. King as to the

In answer to a question from Mr. L. King as to the cost of St. Stephen's Crypt and its probable uses, Mr. Layard said that a sum of £1,953 altogether had been expended, including embellishments and fittings; he believed £830 on embellishments and the rest on fittings. The works were commenced in 1853, they were authorised by his two predecessors, and the cost was met by a vote of the House. The crypt and the baptistry were at present complete and ready for use, by members, if required. It was for the House, not for him, to determine to what purpose the crypt should be applied. He believed the intention of the architect was that it should be employed as a place of worship for the numerous residents in that palace.

# ON LIGHTHOUSES AND LANTERNS.\* By Mr. D. M. HENDERSON.

THE glass used in lighthouse apparatus was nearly all made at Saint-Gobain or Birmingham, and was of the kind known by the name of crown glass. Different mixtures had been employed for the purpose; but M. Reynaud, the Director of the French lighthouse service, now gave the composition as—

Alumir	18.	and	10	xide	0	fir	or	1		•	t	races.
Lime						· •		•		٠		15.7
Soda .									-		•	12.2
Silica												72.1

At Birmingham various mixtured had been tried, of which several examples were given, the following being about an average:—

		_	cwt.	qrs.	lbs.
French sand .			5	0	0
Carbonate of soda			1	8	7
Lime			0	2	7
Nitrate of sods			0	1	0
Argenia			Ò	Ā	Q

English glass was supposed to be of the refractive index of 1.51. That produced at Saint-Gobain had formerly an index of refraction as low as 1.50, but now it was 1.54, and frequent experiments were made to ascertain that the standard was maintained.

The furnace for melting glass was generally rectangular in plan, and was constructed of the most refractoy materials: and the sides were arranged so as to allow of the easy withdrawal of the pots. Six, and sometimes eight, pots were placed in the furnace, arranged in pairs with a firegrate at each end. The flame filled the whole interior of the furnace, and, after circulating round the pots, which were covered to prevent the colour of the glass being injured by dust, or impurities from the coal, found its exit by flues. Great care was necessary in the preparation of the pots, which were made of about one-half new fireclay, and one-half old potsherds finely ground. The length of time a pot would last depended upon (1) the quality of its manufacture; (2) its being slowly and thoroughly dried—a process occupying about six months; and (3) the care bestowed upon it in the furnace, and whilst withdrawn for casting. The average number of castings from each pot was about twenty; and the time the pot was out of the furnace at each casting was about three minutes. It was mentioned that Mr. Siemens' regenerative furnaces were now in use for the manufacture of

lighthouse glass with perfect success. When the metal was ready for casting, each pot was lifted from its seat, withdrawn from the furnace, and carried to the foot of a crane, the lifting chain of which had attached to its end a clip to embrace the pot. A mouth-piece of wrought iron was fitted to the pot before casting, to facilitate the pouring, and the workmen tipped over the pot by means of long handles.

The casting table was circular, and was mounted on a frame, so that by means of a handle it could be turned round, and each part of its outer circumference brought consecutively under the pot of molten metal. The moulds into which the glass was to be cast were arranged round the outside of this table, and were caused to revolve slowly under the continuous stream of liquid glass flowing from the melting pot, so that each mould was filled in succession, thereby enabling the immediate return of the empty pot to the furnace. The moulds were of cast iron, of a uniform thickness of §in., and were supported on feet cast on, the size being such as to allow §in. thickness of glass all round for the grinding process. The small lens-rings and prisms were cast in one piece, but the larger ones were cast in segments. The large belts, or central lenses for fixed lights, were generally cast flat, and were afterwards bent on a saddle to the required curve in a kiln.

Sand, emery, rouge and water were the four necessaries for glass grinding and polishing. The sand had to be applied with abundance of water, until it lost its cutting qualities. The emery, after being ground to a fine powder, was agitated in water, and the mixture was passed through a series of vats or tubs, so that the emery was divided into as many qualities as there were tubs, the coarsest being deposited in the first tub, the finest in that furthest from the supply. The rouge, which was an oxide of iron, was prepared from the sulphate, and was separated into qualities by means of water tubs, as in the case of the emery. The glass of optical apparatus was ground on horizontal circular tables, securely fastened to the tops of wrought-iron vertical spindles, which received motion from the main shafting in various ways. The surfaces of these tables were divided out, like the face plate of a lathe, to receive the different sizes of "carriers," or supports of cast iron, which were bolted to them, and were arranged to hold the lenses or prisms to be ground. Plaster of Paris was then laid on the "carriers" in bands, the bands being reduced to the exact size by turning the table round under a gauge secured to the framing of the machine. The glass was laid on these strips, and was secured in place by means of pitch, care being taken, in the larger sizes, which were ground in segments, to place a thick ness of pitch between each joint, so that glass did not touch glass. A detailed account was given of the method of grinding a belt, or central lens, of a fixed light, and also of grinding a bull's eye or central piece of an annular lens.

The various sizes of catadioptric lights were next given in detail; and it was stated that, in order to produce a distinction between different lights, some were fixed and others revolving, while there were many combinations of the two classes. Again, there were modifications to render fixed lights intermittent, and colours had also been employed, to both fixed and revolving lights.

In reference to the method of mounting the lenses and prisms, it was remarked that sea-lights, on account of their size and weight, were on account of their size and origin, necessarily divided into several portions. The section of the apparatus, consisting of lower prisms, lenses, and upper prisms, gave a prisms, lenses, and upper prisms, gave a convenient division into three tiers, each of which was subdivided into panels of a convenient size. In a first order fixed light, the circumference was divided into eight panels of 45deg. each, which were made of gun-metal racks, or side pieces, formed to receive the lenses or prisms, these side pieces being connected together by gun-metal segments of rings at the top and bottom. The author then proceeded to describe minutely (1) one segment of a first order light, in which all the joints of the panels were vertically over each other; 2) an arrangement with inclined lens-panels, the upper prism panels being so placed that their joints did not come vertically over those of the lower prism panels; (3) a first order apparatus where the upper and lower prisms were fixed; (4) an eight-sided revolving light, collecting the whole light into eight beams of parallel rays : and (5) a first order apparatus, commonly called a "fixed light varied by short eclipses," a title which

an eclipse, the same phases being continually repeated.

repeated.

The construction of the panels was referred to in detail; and it was observed that, when the fitting was finished, the panels were taken to the erecting shed, where they were erected on their pedestals, or on, what was more convenient, a revolving table, specially constructed so that each panel, or part of a panel, could be brought in succession opposite the erecting post. The prisms were passed into their places, one end covering plate of the panel to be set being removed, and wooden wedges were used to support the glass and enable it to be accurately adjusted in its position by means of internal observation, as explained by Mr. Chance in his paper. When the prisms were adjusted, plaster of Paris was applied at all the corners, to retain the prisms in their correct position, and, when fairly set, the wedges were removed and the remaining spaces filled in with best red lead putty.

The arrangement of panels generally adopted was that of placing one panel over the other, so that the joints should be vertically over each other. It had in its favour simplicity, a minimum loss of light, a minimum cost, and strong, convenientshaped panels. These advantages had been considered of such importance, that in France this method was still adhered to, and all the lanterns were constructed with vertical standards placed in front of the obscuration caused by the sides of the panels. This plan, however, rendered as many points, on rather small arcs, on the sea as there were standards in the lantern, to be illuminated with a considerably weaker light. late Mr. Alan Stevenson was the first to introduce inclined lens-panels, with a view to equalize the distribution of light on the sea, but he was no doubt well aware that the total loss of life would be increased. Inclined standards had been adopted in several instances, but without any alteration in the optical apparatus. The horizontal divergence, resulting from the size of the burner in a particular case alluded to, might be taken at 6deg., and the standard was inclined over an angle of 7 deg. in plan, so that when an observer was placed in front of the standard, it nearly stopped off the light from him throughout its entire height, commencing on one edge of the flame and finishing on the other, thus obstructing much light which had successfully passed through the apparatus. The lantern of Mr. Jas. N. Douglass, M. Inst. C.E., the engineer to the Trinity House, was designed to render impossible a correspondence, or optical coincidence. between the framing of the apparatus and that of the lantern. In the author's opinion, this lantern was expensive, from the amount of workmanship of a costly class, and from the glass cut to waste.

An arrangement had been designed by the author with a view to obviate the objections to previous methods. The first consideration was the optical apparatus, and it was apparent that a minimum amount of light was stopped by vertical panels, and that it was possible to divide the pre-vious large obscurations into a greater number of smaller ones, thus equalizing the light without increasing the total obscuration. By excentering, or placing the various tiers of panels so that their joints did not come vertically over each other, each previous obscuration was divided into three. The amount of excentering necessary depended upon the size of the flame, so as to enable one obscuration to be completely passed before entering upon another. In a first order, for example, the panels were 45deg. each; and, as there was modiate rack in the prison panels, there was a space of  $22\frac{1}{2}$  deg. between each obscuration. Each large obscuration could be divided into three small ones, which, if placed at intervals of 74deg., would never allow more than one obscuration to be visible The next consideration was the lantern, at a time. which, when arranged with excentered panels, was rendered less rigid, owing to its weight not being transmitted continuously downwards, as was the case with vertical continuous standards. This want of rigidity would be objectionable in a light illuminating the whole horizon, but in those illuminating from 180deg, to 270deg. (which were by far the most common), the dark are could be filled in with solid iron plates, by which any amount of rigidity could be obtained. By the substitution of triangular frames in the central tier, it was still possible to retain the upper and lower panels excentered, and to render the framing perfectly rigid; in fact, more so than with the vertical continuous bars of the old lanterns.

in fixed light varied by short eclipses, "a title which did not convey the actual effect, as the fixed light first order lantern with inclined standards, (2) of was followed by an eclipse, then a flash, and next the lantern to which the French engineers adhered

<sup>\*</sup> Institution of Civil Engineers.

for all apparatus burning oil, and (3) of the lantern arranged by the author to ensure the most uniform distribution of light.

The three principal varieties of lamps in use for sea lights were the mechanical, the high reservoir, and the pressure. The mechanical were the most general, being used in Scotland, France, and many foreign countries. The oil was forced over the burner by pumps, which were worked by clockwork placed underneath and driven by a weight. One of the best high reservoir lamps was that designed by Captain Nisbet, of the Trinity House, and which had been applied to several English lighthouses. Lamps of this class were not, how-ever, applicable to revolving lights, or those illuminating all the horizon, on account of the obstruc-tion of light that would be caused by the reservoir. The pressure lamp of M. Degrand, of Paris, was next noticed. In it the oil was forced over the burner by means of a weight pressing directly on the surface of the oil. It was found that the large space between the piston and the cylinder in this lamp rendered the leather packing liable to turn over when the oil got heated, and softened the leather; added to this, there was no provision for varying the weights on the piston. To meet these objections, M. Masselin designed a lamp with external weights, which gave excellent results, and had the advantage, not possessed by the high reservoir lamps, of being equally well adapted for fixed and revolving lights, whether the whole horizon was illuminated or not. This lamp was minutely described; and in the next section of the paper an account was given of a first order clockwork, consisting of two trains of wheels, one for driving the apparatus, and the other for driving a flywheel with adjustable vanes for regulating

In conclusion, the means adopted for lighting the entrance to Odessa harbour were described. At the extremity of one breakwater a tower was built, to contain a fourth order optical apparatus fixed for 270deg., with a metallic reflector for the remaining 90deg. At the extremity of the other breakwater a beacon was erected, but it was required that a light should be shown without there being a lamp, or any metallic reflector at that place. Accordingly, a sixth order holophote was placed in the tower, to collect all the light from its lamp into one beam of parallel rays, which was thrown across the entrance to the harbour to illuminate the beacon, producing thus what was called an apparent light. On account of the distance of the beacon from the holophote-300ft.—much light was lost, and the divergence of the beacon was small, but ample for what was required, as it was placed low, and a range of only about one mile was required.

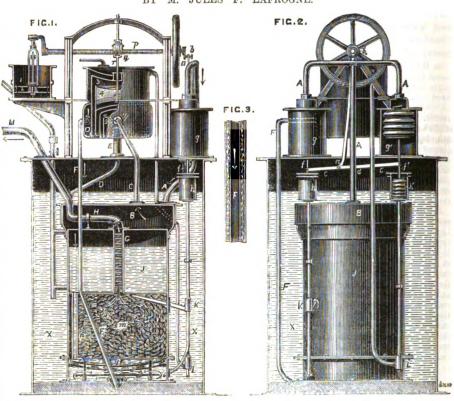

The communication was accompanied by fiftysix diagrams, and by six sheets of carefully executed drawings to a reduced scale.

# MANUFACTURE OF GAS.

N invention, relating to the production of gas for lighting and heating purposes, by the carburation of atmospheric air, has just been patented by M. Jules François Lafrogne, of 23, Boulevard de Strasbourg, Paris. The characteristic features of the invention are the following: -- First the apparatus is combined with a motor, which obtains its power from a portion of the gas produced, and which directly feeds the carburator or hydrocarbon reservoir with the atmospheric air necessary for the generation of the gaseous vapour. Second, the motor allows of establishing a circulation of water in the jacket or casing, around the carburator, for the purpose of absorbing the cold resulting from the evaporation of the essence or hydrocarbon. The cooled water is sent into the motor, in which it is re-heated by serving for the condensation, and it returns into the jacket, restoring the lost heat to the essence, so that the essence being constantly re-heated by the water in proportion as it is cooled, there is no interruption or diminution in the production of the gas. Third, the air is drawn by bellows worked by the motor, heated in an annular space surrounding the motor, and then sent into regulating bellows, in which it accumulates under a nearly constant pressure. Fourth, the air becomes saturated with carburetted vapours in traversing a series of layers of fiannel and wood shavings, or sawdust, which are soaked with the essence by capillary attraction, and which, besides, is always damped therewith by means of a pneumatic injector worked by the motor. The saturated air rises through a series of alternate layers of flannel, wood shavings, and iron filings, filled with sawdust or other substance isolating

# FOR MANUFACTURING APPARATUS GAS.

BY M. JULES F. LAFROGNE.

which deprive it of the excess vapours and nonvolatilized globules; it afterwards issues in a suitable degree of saturation by a pipe, from which it is distributed for consumption.

In our engraving, figs. 1 and 2 are front and side views of the apparatus in sectional elevation. Fig. 3 is a longitudinal section of part of the pipe which conducts the air to the carburator. The motor employed is worked by hot air and cold air, and is composed of a cylinder 1 provided with a piston 2, and of a cold air chamber 3, enclosing a hollow piston or movable pan 4, and surrounded with a piston or movable pan 4, and surrounded with a cold water receiver. The movements of the two pistons 2 and 4 are effected so that when the dilated air has raised the first-named piston 2, the other piston 4 rises suddenly to draw hot air into the cold part of the chamber 3, which aids the descent of the first piston 2. The lower part of the chamber 3 forms a combustion chamber 5 which is provided with a chimney, and which is heated by a burner E supplied by a branch o from the outlet pipe H of the carburator. The piston rod of the motor is connected by a crank to a shaft p, which by a cam q and rod r is worked by the rod of the hollow piston of the chamber 3. The rod which works the hollow piston actuates the bellows, either directly or through a lever or connecting rod.

The motor gives motion to the rod a, by means of the crank b, and the motion of the rod a causes the oscillation of the beam c, upon its centre of suspension d. The oscillating movement of the beam c causes the alternate ascent and descent of the two piston rods f f<sup>1</sup>, and, consequently, the successive compression and dilatation of the four bellows g g <sup>1</sup> and h h <sup>1</sup>. The former of these, g g <sup>1</sup>, cause the continuous aspiration and repulsion of the air within the cylinder; the two latter, h h 1, are for another purpose, which we will presently state. The air repulsed continually through the pipe A flows into the upper partition B of the cylinder, and thus forms a regulating reservoir. From thence the air escapes by the pipe C, and enters the annular space D, which surrounds the hurror E. The air receives an elevation of terms. burner E. The air receives an elevation of tem-perature while within this annular space, which favours its carburation, and its combustion afterwards; then it proceeds in a heated state through the pipe F to the lower partition of the carburator-This pipe F, of which a portion is shown separately in longitudinal section in fig. 3, is double. The interior pipe serves for the circulation of the hot air, while the space left between the two pipes is

This arrangement of the tube F has th heat. effect of preventing the cooling of the air in it passage from the annular reservoir D to the car burator.

On proceeding from the pipe F, the hot air tra-On proceeding from the pipe r, the nor air universes the little wad of flannel i, then circulates between the plates j, k, and l, following the course indicated by the arrows. The combination of these plates, alternately arranged, forces the air to divide itself, while hindering its progress, and to become saturated with the volatile properties to become saturated with the volatile properties of the hydrocarbon, which it thus thoroughly traverses. Above the dust plate l the air completely traverses the body or layers m of wool and wood shavings, impregnated with hydrocarbon or volatile oil. Then, after having undergone the further carburation from the layers of saturated flannel and filings within the pipe G, it escapes in a fit state to be used for lighting purposes, through the tube H, which distributes it as required.

The hydrocarbon is contained by the reservoir J, from which it flows through the tube n, to bathe the plates j, k, l, and the lower part of the body of wool H. This mass, in addition, always receives an injection of the hydrocarbon at its upper part, from the little pump, actuated by the bellows h above referred to. The second bellows, h l, draws cold water from the lower part of the exterior reservoir X, by means of the pump L, to force it to the upper part of the motor, and thus assist the cooling of the latter. A branch pipe o feeds the burner E.

After having filled the reservoir J with the carburating liquid-an essence of schist or petroleum or other hydrocarbon—the apparatus is put in action by the hand, and when in this manner a small quantity of gas is produced, the burner E is lighted. In a few minutes the motor will commence to work, and the apparatus will act of

A Parliamentary return shows that in the year 1868, 6,805,659cwt. of foreign sugar were imported into the United Kingdom, and entered for home consumption here. 2,962,420cwt. are returned as coming from Cuba, the largest importation ever received from that source; 1,210,414cwt. from Brazil; nearly 1,700,600cwt. from the Continent of Europe. The total import of foreign sugar in 1867 was 7,149,940cwt., and of sugar from all quarters entered for consumption here 11,697,328cwt. The total for 1868 is stated at 11,892,832cwt., but this is subject, we believe, to deductions for over entries and exports on drawback. A PARLIAMENTARY return shows that in the year

# TRIAL OF THE "INCONSTANT."

VESTERDAY week the "Inconstant" underwent her first trial of speed at Stokes Bay. This vessel, it will be remembered, is the first of a special class of armed ships, whose object is speed a special class of armed ships, whose object is speed rather than power. She is sister to the "Volage" and the "Active," recently launched from the Thames Iron Works yard. Since she was launched, the "Inconstant," which measures 4,066 tons, has been fitted by Messrs. John Penn and Sons with very fine engines of 1,000 (nominal) horse-power, and he have armed with six 61 to gauge here. and has been armed with six 6½-ton guns on her upper deck, and ten 12-ton guns on her main deck. Half an hour after her start from Spithead upon the present occasion her screw was doing 64 revolutions er minute, and at half-past ten it had reached 70. The first run of the measured mile to the westward was made in 3min. 37sec., which is at the rate of 16-520 knots an hour; the second to the east in 3min. 53sec., or the rate of 15-451 an hour. The mean of the two runs was 16.0205 knots, which is more than a knot in excess of the contract rate. No doubt, however, when the "Inconstant" comes to run her official trial with all her stores on board, this speed will be somewhat reduced, although, on the other hand, it is to be taken into consideration that her engines will be in a better condition than they could possibly be at the builder's trial when 73 was the maximum number of revolutions attained. There are eleven boilers, heated by thirty-two large and six small furnaces, to drive the surface condensing engines, the cylinders of which are 112in. in diameter, and are on Penn's doubletrunk principle. The trunks are 41in. in diameter, and the cylinders have an effective diameter of 1044in. The length of the stroke is 4ft., and the diameter of the axle 191in. The propeller is a "Griffiths," with two blades, set at a mean pitch of 24ft., but capable of variation to 21ft. and 27ft. The water is circulated through the condensers by a pair of centrifugal pumps, which, with their separate engines, are notable as fine specimens of workmanship. In the condensers there are 12,552 metal tubes, a number, we believe, quite unprecemotal tubes, a number, we believe, quite unprecedented. The pressure at full steam was 26, and the vacuum showed  $27\frac{1}{2}$ deg. The horse-power being, as we have said, 1,000 nominal, that indicated should have been, according to the terms of the contract with the engineers, 6,000; but it attained to 6,600, or 10 per cent. more than the amount stipulated for. The lowest temperature in the form state halo was 31deg, and in the form the fore stoke-hole was 81deg., and in the after 90deg.; but in the firing up it rose to 140deg. forward and 148deg. aft. The only fault that could forward and 148deg. aft. The only fault that could be found with the machinery was in the setting of the screw, which had a tendency to go on or go back—at any rate to keep moving— when the engines required it to stop. This is, however, no novelty in new screws, and a very little attention will set it right before the engineers hand over their work to the Admiralty. After a few trials of the screw and the command over the helm, the "Inconstant" was taken into harbour, the whole having proved a most creditable trial.

# A NEW DECORATIVE MATERIAL.

THE slowness of painting operations in buildings. the obstruction caused by workmen, and the disagreeable smell from fresh paint, are great inconveniences inherent to the present mode of painting and decorating. To remedy this, M. Jean painting and decorating. To remedy this, M. Jean Marie Lasché, of No. 23, Boulevard de Strasbourg, Paris, has just patented an invention, the object of which is chiefly to dispense with painting operations in the house or room to be decorated, and to prepare the painting at a factory or shop, so that it can be applied to walls or other surfaces by ordinary hangers or layers, without giving rise to disagreeable smells. The invention consists in producing the painting upon tin foil. M. Lasché takes thin tin foil, which possesses great flexibility, and spreads it upon glass, taking care to damp the glass in order to facilitate the spreading and re-tention of the foil. The foil thus spread consti-tutes a very smooth surface, on which the inventor paints or colours in oil, either plain or ornamental, as on walls or wainscots. It is allowed to dry, and is then varnished. This portable painting, when removed from the glass with its lining of tin, is ready to be applied in a house or otherwise. This new covering or hanging is wound on rollers like paper hangings, but it differs from them, inasmuch as the colouring or painting is on tin and in oil; the back or tin lining constitutes a waterproof surface, and the tin, owing to its great flexibility, can be adapted to the configuration of all mouldings or irregularities. Before applying

the tin hanging or covering, a waterproof mixture is spread on the wall or surface to be decorated, and the hanging is then cut and applied, being made to follow the irregularities of the mouldings and ornaments. This tin covering may also replace gilding, the gold being applied on the tin foil with the ordinary preparation. It is dried and cut, and after having had a waterproof mixture spread on the ornaments or surface to be decorated, the pieces of tin gilding are applied to them. The advantage of this tin gilding over ordinary gilding on metals is that it does not oxidize, while ordi-nary gilding on metals soon becomes spotted or tarnished. This invention thus constitutes, as it wore, a new process of decorative painting, which dispenses with all labour at the place of application, except simple hanging or laying. We have by us some samples of this new material, which are exceedingly appropriate and effective.

### THE BERMUDA FLOATING DOCK.

THOSE of our readers who watched the progress THOSE of our readers who watched the progress of Mr. Campbell's patent floating dry dock, at the works of his firm at Silvertown, will be glad to learn that a memento of this fine structure still remains with us. This consists of a very fine chromolithograph, which has just been published by Mr. John B. Day, of Savoy-street, Strand. The drawing, which is most effective represents the "Warrior" John B. Day, of Savoy-street, Strand. The drawing, which is most effective, represents the "Warrior" docked, without the caissons; the scene is laid at Plymouth, where the original photographs were taken. This dock was designed for docking ships of the "Bellerophon" class when waterlogged beor the Beisrophon class when waterioged between the caissons, and is capable of lifting without the caissons a vessel of 8,700 tons weight, which, with the weight of the dock itself, 8,000 tons, gives a total displacement of 16,700 tons. The length of the dock over all is 381ft., breadth over all 123ft., inside width 83ft., depth 74ft. The dock was launched on September 3 last, and, we understand, is shortly to be forwarded to its destination. Mr. Day's lithograph is an excellent example of the art of chromolithography, and a faithful representation of the dock

### STATISTICS OF BOILER EXPLOSIONS.

IN consequence of the frequency of boiler explo-A consequence of the frequency of botter expined sions in the manufacturing districts of Lancashire and Yorkshire, a meeting of cotton spinners, engineers, and other users of steam power, was held in the Town Hall, Manchester, on January 23, 1855, when an association was formed "For the Prevention" of Steam Boiler Explosions," and a committee of management appointed, of which the late Mr. Henry of steam Boner Expiosions, and a committee of management appointed, of which the late Mr. Henry Houldsworth was president, and Messrs. Ashworth, Bazley, Fairbairn, and Whitworth, vice-presidents. It was not, however, till the latter end of March of the same year, when Mr. R. B. Longridge was appointed Chief Inspector, that the Association commenced operations. On December 31, 1855, the number of members enrolled was 269, with 920 boilers; and, at the close of the year 1859, had increased to 530 firms, with 1,619 boilers. From this date, however, a decrease took place in consequence of the formation of "The Boiler Assurance to the system of periodical inspection as carried out by the original Association,—undertaking to make good any damage that might result from the explosion of a boiler or the collapse of flues. The formation of such a company was first proposed by Mr. sion of a boiler or the collapse of flues. The forma-tion of such a company was first proposed by Mr. Thomas Forsyth, manager at Messrs. Sharp, Stewart, and Co.'s works; and, in the spring of 1858, a provisional committee, consisting of himself and a few of his friends, was formed with this object. Little progress was, however, made, owing to the untimely death of Mr. Forsyth shortly afterwards, by the explosion of a locomotive boiler at the works

of his employers.

Towards the close of the same year, the question of boiler insurance was submitted to the Committee of the Association before-mentioned, but was un-favourably received, the whole of the members prenavourably received, the whole of the members pre-sent being opposed to the principle of insurance. Mr. Longridge, however, took a different view of the suggestion, and believing that a company which undertook the inspection of boilers combined with insurance could not, if well managed, fail to succeed, insurance could not, if well managed, fail to succeed, resigned his appointment with the view of forming such a company. In the spring of 1859, the organization of the Boiler Assurance Company was completed; and, by the end of the year 1860, the Company had received proposals for the insurance of 3,149 boilers, while, at the same date, the number of boilers under the inspection of the original Association had fallen as low as 1,360. It may also be here mentioned that, in the year 1858, an Association for the prevention of steam boiler explosions was

bers becoming connected with the Steam Boiler Assurance Company.

The success of the latter led to the formation of

The success of the latter led to the formation of two similar companies, one of which originated with the principal iron masters of South Staffordshire in 1862, in consequence of a boiler explosion which occurred near Bilston, by which twenty-nine persons lost their lives. The same company has since established a branch in the north of England, principally appropried by the iron masters and coal established a branch in the north of England, principally supported by the iron masters and coal owners of that district. The other company was formed in London in 1864, but subsequently transferred its head-quarters to Manchester. The number of boilers enrolled with the "Association for the Prevention of Boiler Explosions" had, as already stated, fallen from 1,619 in 1859, to 1,360 in 1861, but subsequently increased to 1,455 at the close of 1,861. subsequently increased to 1,415 at the close of 1864, when that Association also adopted the principle of insurance, the advantage of which has since shown insurance, the advantage of which has since shown itself by a considerable accession of members. About the same time (January, 1865), the Boiler Assurance Company was converted into a Limited Liability Company, under the title of "The Boiler Insurance and Steam Power Company, Limited." The following shows approximately the number of boilers under the inspection of each of these Associations on December 31, 1868:—

n December 31, 1808:—	
The Boiler Insurance and Steam Power	
Company, Limited ·	10,900
The Midland Steam Boiler Inspection	
and Assurance Company	2,600
The National Boiler Insurance Com-	,
pany, Limited	2,000
The Association for the Prevention of	
Steam Boiler Explosions	1,900
Total	17,400

Total . . 17,400

In the course of the last ten years there have been in the United Kingdom not less than 495 boiler explosions, by which 786 persons have lost their lives, and a yet greater number have sustained serious injuries. It may therefore be stated in round numbers that 50 explosions, causing 80 deaths, occur annually. During the same period (ten years) 16,411 boilers have been insured, and periodically inspected by the Boiler Insurance and Steam Power Company, of which only 15 have exploded. Of those inspected by the other companies, 11 have exploded, viz.:—

Midland Steam Boiler Ins	spect	ion a	nd	
Insurance Company	٠.			4
National Boiler Insurance	Com	pany		2
Association for the Prevent				
Boiler Explosions .		•	•	5
Total				11

The total number of inspections made by the officers of these companies in 1868 were as follows, viz. :---

Boiler Insurance and Steam Power	
Company	40,952
Midland Steam Boiler Inspection	•
and Insurance Company .	11,900
National Boiler Insurance Company	6,000
Association for the Prevention of	
Steam Boiler Explosions .	6,588
Total	65 440

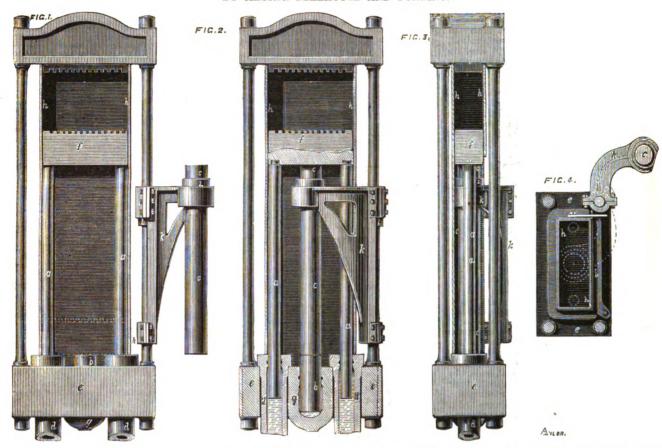

The rates charged by the first-named company, which extends its operations to all parts of the United Kingdom, average 20s. per cent. per annum for insurance, including periodical inspection, and 17s. 6d. per boiler per annum for periodical inspection alone. The rates of the other companies differ but slightly. The expense being so trifling, there is little or no excuse for those whose boilers explode through neglect of inspection; but so long as boiler explosions continue to be regarded as "accidents" for which no one is responsible, many of the users of steam power will rather incur the risk of explosion than pay a fee, however small, for the inspection of their boilers. That such inspection has been of great service in preventing explosions is proved by the detection of the numerous dangerous defects enumerated in the reports published by these companies. The rates charged by the first-named company,

A PITTSBURGH firm have recently made a steel A litter of the man have recently made a steel roller for rolling metals at the Philadelphia mint, which, after a test of several weeks, has been pronounced superior to the Prussian. It is said to have been hardened by a new process, discovered by the manufacturers. Another roller has been ordered of the same firm for the same mint, to be used in selling right. rolling nickel.

On April 23, about 11 a.m., a train on the Long Island (New York) Railroad crossed a broken rail and ran off the track while at high speed, and the last carriage, which contained fifteen passengers, was instantly broken to pieces. Eight of the passengers and a brakesman were killed outright, while the others were scriously injured. Every year a disaster involving loss of life occurs on this railway, and this latest one has created much indignation the officers of the road being agreeing required. the officers of the road being severely censured

# HYDRAULIC PRESS.

BY MESSRS. BELLHOUSE AND DORNING.

# HYDRAULIC PRESSES.

MESSRS. BELLHOUSE and DORNING, of Manchester, engineers, have recently patented some improvements in hydraulic presses. They employ in one arrangement three rams with their respective cylinders, the rams and cylinders being ranged in line with the others, the two outer rams and cylinders being of a length suitable to the entire lift of the press table. The centre cylinder is made suitable for a ram of a greater diameter than the two outer rams, the stroke of the ram being considerably less than that of the outer rams, the central cylinder being cast in one portion with the lower crosspiece of the piece. When the compression of the material is commenced the two outer rams are forced up by the pumps, the central ram remaining stationary, the action of the outer rams continuing until such time as a greater pressure than the outer rams can communicate is required, at which time an intermediate piece is placed between the upper part of the central ram and the lower part of the press table or follower, and the three rams are forced up simultaneously to produce the final compression, the intermediate piece transmitting the thrust of the central ram to the follower. The intermediate piece is of metal, and of a form similar to an ordinary press ram, and is suspended from a crane swivelling around one of the press columns. By the employment of the intermediate piece, the inventors are enabled to use a shorter central eylinder, and pumps of a less capacity than would

otherwise be required.

The press we have illustrated is adapted for the packing of fibrous materials, as, for example, cotton, and is fitted with a box to contain the cotton. The details of construction of the box, as well as portions of the press, are not represented, presenting no features of novelty. Fig. 1 is a front elevation of a hydraulic press constructed in accordance with Messrs. Bellhouse and Dorning's invention; fig. 2 is also a front elevation, partly in section; fig. 3 a side elevation, and fig. 4 a plan. In the figures, a a are two outside rams, b is a central ram, and c is the intermediate piece. The two rams a a work in the cylinders d d, which are fitted into the foundation casting e, the upper ends of the rams being connected with the follower f, and the central ram b works in the short cylinder g, which is cast in one piece with the foundation piece e. The sides of the box in which

the cotton is placed are shown at h h, and the box is fitted with doors which can be opened when the pressing is completed, as is usual; and also with a door, shown at i, in fig. 4, which door can be opened previously to the completion of the pressing, and which, when opened, admits the intermediate piece c to be moved into position under the follower. The intermediate piece is carried by the crank k, which is fitted to swivel around one of the columns of the press, being supported by the collar l formed on the column. The piece c is sustained on the crane by the collar 2, which rests upon the boss formed on the end of the crane, and the piece is free to slide in the boss when a force is applied tending to move it in an upward direction. The proportions of the crane are such as that when the intermediate piece is moved into position under the follower f, as shown by the dotted lines in fig. 4, the longitudinal centre line of the piece will coincide with the centre of the ram.

The action of the press is as follows:—The box having been filled with cotton, it is placed in position in the press and the water pressure is admitted to the two outer rams a, by which means the follower f is forced upwards from the position indicated by the dotted lines in fig. 1 to the position as represented by the full lines, and the cotton contained in the box is thus compressed into a smaller compass, the force required to effect the compression being as great as can be conveniently applied to or transmitted by the rams a. The door i is now opened, giving access to the lower portion of the box, only without interfering with the enclosure of the cotton, that is, the door extends in an upward direction to the under side of the follower f, or a little over. The crank k is now swivelled into the position as represented in fig. 2 and by the dotted lines in fig. 4, and the intermediate piece c is thus brought directly over the ram b, the upper end of the piece being in contact, or nearly so, with the under side of the follower. The water pressure is now admitted to all the three rams simultaneously, and the follower is forced upwards with the increased pressure due to the action of the ram b for the remainder of the usual lift of the follower or until the cotton is compressed to the required extent, the intermediate piece acting for the time being as a continuation of the ram. The compressed cotton is now formed into a bale in the usual manner, and the piece c is swivelled or moved outwards in order to admit of

the follower being "run down," the succeeding operations being substantially as already described by us.

Although cotton only has been mentioned when

describing the action of this press, it may be employed in the packing of other materials or substances. A short cylinder similar to that marked b in the engravings, acting in conjunction with a movable intermediate piece, may be employed in presses having more than two cylinders and rams of the ordinary construction and proportions, or similar to the rams a a and the cylinders d d, as may be found convenient.

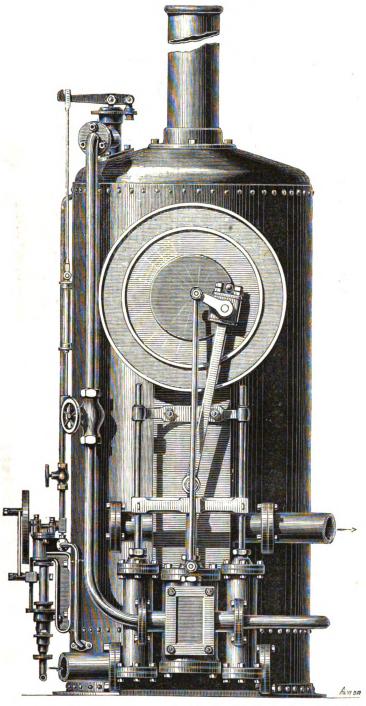

# CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

A T the ordinary meeting of this society, held at their rooms, Whittington Club, on Wednesday week, the president, Mr. B. Haughton, in the chair, a paper, upon "Water Supply to Towns and Villages," by Mr. George W. Usill, was read. The author, after tracing the history of water supply throughout all ages, and describing the great works of the ancients, proceeded to investigate the phenomenon of rainfall, and its effect upon the British Isles. By a very lengthy resume of the experiments which have been made during the past two centuries by the most eminent scientific men of the period, the author treated the questions of evaporation and absorption—the chief agents at work to diminish the available supply from the rainfall. He then considered the various methods of obtaining a supply of water from drainage or collecting areas, from rivers and streams, from springs and from wells, and the principles involved in works from the two first sources, leaving the other questions to follow with the second part of the paper. At the termination of the paper, a vote of thanks was awarded the author, and a very animated and interesting discussion then commenced, in which Messrs. Haughton, Pain, Sefi, Meakin, Roberts, G. J. C. C. Godsman, F.R.A.S., and others, took part. Before adjourning the meeting, the president gave notice that at the next meeting of the Society, June 2, a paper, upon "The Building Stone Used in the Metropolis," would be read by Mr. A. F. Pain; to be followed, June 9, by a paper, on "Steam and other Power Hammers," by Mr. F. H. Roberts, honorary secretary. The meeting was then adjourned.

#### IMPROVED DONKEY ENGINE.

BY MESSRS. A. WILSON AND CO.

# WILSON AND CO'S DONKEY ENGINE.

T is now some ten years since Giffard's injector called the attention of engineers to the advan-tages of a boiler feeder which should dispense with the feed pumps of the engine. Its beautiful sim-plicity at first sight would have led a casual ob-server to say that the days of pumps of every description were numbered, but the result in pracdescription were numbered, but the result in practice has been to stimulate the manufacture of pumps of every form, principle, and design, thus making good the old saying that competition is the soul of trade. Although donkey pumps had been used to some extent for a great many years prior to Giffard's invention, it is only since its introduction that the manufacture of this class of pump has obtained prominence as a specialty and as our has obtained prominence as a specialty, and, as our readers are no doubt aware, they are now about as plentiful and cheap as the well-known "forty shilling watch." They may be divided into two great classes of flywheels and non-flywheels. Of the respective merits of these two classes we do not now intend to speak, but we have no doubt that each has its votaries, and that the flywheel, with its tangible and convenient mechanism, will not be soon superseded by hidden and mysterious tappet notions. We recently met with some good examples

of the flywheel class at the works of Messrs. Alexander Wilson and Co., of the Vauxhall Iron Works, Wandsworth-road, their recent productions possessing points well worthy of notice. An inspection of Messrs. Wilson's works showed us that these manufacturers have now reduced the production of steam pumps to such a speciality that they are turning them out at the rate of ten to twelve per week. This has enabled them to adopt the system of having special tools for executing particular work, and having machines and workmen set apart for the manufacture of particular details. For instance, one lathe is continually boring cylinders, one turning wheels, another finishing connecting rod ends, and so on, through all the various details till they are ready for the fitter to put together. The result of this system is that they are enabled the result of this system is that they are enabled to attain great excellence of workmanship, and yet sell a pump at a price which must astonish some engineers. They successfully solve the problem of how England may yet be able to compete with the cheaper labour of the Continent, for we may mention that Messrs. Wilson send considerable numbers to continental countries, where, in addition to the cost of carriage, they have to compete with Giffard's injector, sold at a price about 30 per cent. less than in England, in con

sequence of its not being patented in some of these

countries.

We have selected for illustration a steam pump of large size attached to a boiler manufactured by Messrs. Wilson, which, while differing considerably from their well-known pattern, contains several points of novelty, and for a flywheel pump gets the machinery into the smallest possible compass without any overcrowding or complication. This pump was started during our visit to the Vauxhall Works, and we were much pleased with its working. A prominent feature is the education working. A prominent feature is the adaptation of the framework to form a capacious air vessel, while the steam cylinder is placed between two pump barrels, which, however, work into the same suction and delivery valves, each set of which are conveniently accessible by means of doors on either side of the pump. The prolongation of the pump rods form very efficient guides to the steam piston rod, all three being made of Bessemer steel. At first sight, objection might be taken to the close proximity of the water barrels having a tendency to cool the steam cylinder, but in practice it is found that when the engine has been running for half an hour without pumping any water, the temperature of the barrels does not sensibly increase. Suction and delivery pipe connection is arranged on each side of the pump, so that the pipes may be taken to the right or left of the pump, according to its position, the other being closed with a blank flange. On board ship, it is, however, often convenient to here one writer to the bilar and convenient to have one suction to the bilge and another to the sea, and one delivery to the boiler, while the other can be used for washing decks, &c. Our illustration shows the boiler supplied &c. Our illustration shows the boiler supplied with a No. 4 pump, attached conveniently to its side, but the large pump can be arranged to supply its own boiler, which is, however, not so convenient as shown in our illustration. It forms an admirable pump for railway stations and in large mills, where repairs have to be done at night and during holidays. The flywheel of the pump is available for driving both lathes and drilling machines. Messrs. Wilson and Co. have just supplied one mounted on wheels for a sugar estate in the West Indies; in fact, it is from the drawings of that Indies; in fact, it is from the drawings of that engine that our engraving was prepared.

# ON INDIAN FIBRES.

BY MR. LEONARD WRAY.

THE subject this evening is that of Indian fibres, a subject which has been frequently brought before this Society,\* and especially by those able and scientific men, the late Dr. Royle and Dr. Forbes Watson, to the latter of whom we are all greatly indebted for the exhaustive manner in which he has treated the subject. I propose to occupy your time but very briefly, as I well know the valuable nature of the discussion which will the valuable nature of the discussion which will follow the opening of this most interesting subject

We cannot avoid dividing our subject into the three great branches which it naturally assumes, viz.:—First, those fine silken fibres so valuable for manufacturing into textile fabrics; second, for manufacturing into textile fabrics; second, those suitable for cordage, &c.; and, third, those adapted only to paper making. And I need not tell you that, to do anything like justice to them, would fill a good-sized pamphlet appropriated to each. Flax and hemp are so largely grown in Europe that we may well leave them out of the question for the present; and I think the same may be said of jute, and others of the same class. The fibre which is now creating a great stir amongst our manufacturers is the "Rheea," so commonly although erroneously called China grass. commonly although erroneously called China grass, as we obtain our supplies almost wholly from China. It is there named "Tchu-mā," and is named in botany Urtica nivea, being of the nettle family. In Assam, a cultivated and a wild variety family. In Assam, a cultivated and a wild variety is found; and in the Malayan peninsula, Penang and Singapore, another variety grows wild, the fibre of which is unusually strong. This has a Malay name, "Rāmee," and is in botany known as the Urtica tenacissima. The partly prepared fibre of the rheea, such as this, is now worth in the market £70 per ton, whilst the beautiful silken fibre, fully prepared, is worth 2s. 4d. per pound, as the fabrics made from it are of so strong and so lustrous a character as to be in universal and so lustrous a character as to be in universal demand. Pity, indeed, is it that this splendid fibre can be obtained only in such small quantities. No other supplies can be looked for, except from China, nor can we expect much from that country either. Its growth and preparation have been tried by most intelligent Englishmen in India, but

' Society of Arts.

they found, first, that the separation of the fibre from the plants was a most difficult and laborious operation; and, second, that the yield per acreper annum was exceedingly small. Indeed, it is said by a gentleman now present to yield only lewt to light of fibre to the acre—a fact which forbids any European from entertaining hope of cultivating it at a profit, which is much to be regretted.

The authors I have alluded to made particular mention of the following plants as yielding fine, silken, and yet strong fibres, viz., the Pederia fœtida, the Jettee, the Moorva, and the pine-apple, each of which they fully describe; and no doubt almost all of them are known to many now present. I quite believe that they each and all of them hold out the promise of amply remunerating any European who will attempt, in a judicious manner, to utilize the beautiful fibres they contain. The Pederia feetida certainly has the most silky and lustrous fibre any one can desire, and its being only in lengths from joint to joint seems the sole objection to it. Still, these joints are often 12in.

apart, whilst the finest Sea Island cotton is not
more than 1in. to 1½in. in staple. Attention
ought, therefore, to be directed to this lustrous
fibre-yielding plant. The Jettee, again, is jointed,
but the joints are sometimes 2it. apart, and the fibre proportionably long. It is a most excellent The pinefibre, and will be sure to make its way. apple, with its beautiful fibre, exists in thousands of acres in the Straits of Malacca, and may be had at Singapore in any quantity for the trouble of gathering, yet no one seems to regard it. This indifference to so tempting an opportunity is really most astonishing, but I imagine it cannot leave the control of the cont last much longer.

Now, the plant which I desire most especially to draw your attention to, is that from which the surpassingly beautiful Manilla handkerchiefs are made. Who has not seen or heard of the long celebrated "Pigna" cloth, which can only be purchased at extreme fancy prices? This magnificent chased at extreme fancy prices? This magnificent production is made from the fibre of Mindanao (Bromelia), in fact, the Bromelia penguin, a kind of wild pine-apple, which is exceedingly abundant in both cast and west. The late Mr. Temple, formerly Chief Justice of British Honduras, some years ago, exhibited a quantity of the fibro to this Society, and he called it "silk grass;" and some present may remember how long, how strong, and how silken it was. We may search the world through, and not find another plant capable of yielding us so rich, so abundant a supply of a fibre, which in quality cannot be excelled. That is a plant which we may look to, to provide us with a very large amount of the very best quality of fibre. I believe this plant has hardly been spoken of; I doubt whether it has been named. It is more easily obtained, and the yield of fibre is very large because each leaf is a mass of fibre, mixed with vegetable matter, which is easily expressed in the green state. Dr. Forbes Watson told me that he looked upon the rheea as the fibre of the future; but if it be true that it only yields lewt. of fibre per acre, you will, I am sure, agree with me in thinking that it cannot be the fibre of the future, unless it can be grown cheaper and in greater quantity than we yet know of. But the fibre to which I allude can be grown exceedingly cheap, and the manufacture involves no difficulty. not know the exact mode by which Mr. Rutledge separated the fibre, but I believe it was on the principle of the thrashing machine, the plant being passed at a slow rate along a platform having a yielding surface, through rollers and beaters; and, when this was done with the plant in a green state, it came out at the other end of the machine very good fibre, which was improved by repeating the operation. A stream of water is used to wash the pulp away as it was expressed from the fibre. These are the principal textile fibres to which I have to draw your attention.

I come now to cordage fibres, and that is so vast a subject, that I feel I ought scarcely to introduce it on this occasion; but the point to which I will call your attention, lastly, is that of fibres adapted to paper making. With respect to paper making, we can be satisfied with a very different character of material altogether, and almost anything of a fibrous nature would answer the purpose. I suppose almost all the plants of England have been tried, and some of the patents are very laughable. I have seen specifications of patents containing columns of names of almost every plant in England. Amongst others, there is the nettle; but with reference to Indian productions, there are plants which yield valuable productions, besides fibre. But there is one plant I was particu-

larly struck with: that is the common canna, one of which often grows as high as 14ft. The whole stalk and leaf are one mass of fibre, so much so that, on cutting down one of these plants in my conservatory, I found the leaves were full of beautiful fibre. The root furnishes that description of arrowroot which is called "Tous les Mois," and is described by chemists as the most nutritious of all the starches—more nutritious than the best arrowroot that comes into the market. That is the first product of the plant; the second product is the fibre resulting from the roots; and the third, the fibre from the stalks and leaves of the plant itself. If we get a double product from such a plant as this, that is getting really a great advantage, and at a cheap rate; and the cheaper you get fibrous matter to make your pulp, the better it will be for all parties.

It may be interesting to you to know in what form this fibre for paper making can be best sent to this country. It is said we cannot have paper mills in India, because, as we see them in England it costs a great deal of money to build and furnish the machinery. We must take into consideration the different kinds of paper made. If we go in only for that kind of paper which newspapers are printed on, that is a simple thing. I saw that kind of paper made twenty-five years ago, in the mills of Mr. Marshman, the proprietor of the "Friend of India," and I was struck with the simplicity of the thing. In the factory, which was a very plain building, a number of women and children were seated, with blocks of wood before them, cutting up old gunny bags to pieces, and those were washed and made into pulp. The pulp was passed between cylinders heated by steam, and the paper was made from it. The paper is worth from 3d. to 4d. per lb., and is well adapted for newspapers. Only consider the quantity of paper that we send to India! Why should they not that we send to India! Why should they not make their own paper? I recollect on one occasion, Dr. Riddell exhibited in this room some fibre from the ochre plant, which he called a paper making plant. That plant is fibrous from one end making plant. That plant is fibrous from one end of it to the other; and Dr. Riddell showed me some paper which was made from it by the simelest process possible—merely pounding it in a spooden mortar, and turning out the paper at once. When we know this, we may well ask, Why not make paper in India? I have here a specimen of a pulp made of Esparto grass, and converted into pulp in Spain. It is worth £20 per ton in the market. That is the form in which I should recommend those who would not make paper in India to send it here. If it is made in larger slabs India to send it here. than this it is difficult to dry. If theroughly dried it will keep for a thousand years uninjured, but, if not quite dry, it is liable to change colour, as this has done; but in this condition little more requires to be done with it to make it into paper.

# ON THE OCCULTATOR.\* By Professor Lewis R. Gibbes.

IN the years 1848—1854, I was much engaged in observing occultations of fixed stars by the moon, and as a means of obtaining the approximate times of disappearance and reappearance with less labour than by calculation, I devised and constructed, in 1849 or 1850, an instrument for that purpose, to which I gave no special name. This instrument is still in my possession, but not in use, as certain parts, presently to be mentioned, have deteriorated with the lapse of time.

The Rev. Thomas Hill, of Cambridge, Mass., has published in the November number of this Journal, a description and figure of an instrument for the same purpose, invented by him in 1842, and called by him the occultator. As the two instruments have the same end in view, there is a general agreement in plan, but the details differ. Mine is founded on the well known method of orthographic projection usually adopted in projecting eclipses and occultations, and I have published no description of it, nor do I propose doing so at the present time; but I wish to mention now, the devises I adopted to overcome certain difficulties which present themselves in both instruments, and the following explanations will be sufficiently intelligible, without a figure, to those familiar with the subject.

Mr. Hill finds the desired projection, on the plane of the instrument, of any point above that plane, as the extremity of a steel rod, by means of a silk thread stretched on a brass bow, set on a triangular base, and made normal to the chart or plane of the instrument, by screws in the base. I

"American Journal of Science and Arts."

effect the same end very simply and readily by the following expedient, based on the optical principle that an incident ray and the corresponding reflected one coincide when they are normal to the reflecting surface. A bit of a good glass mirror with parallel surfaces, and a few inches square, having two lines traced on it with a writing diamond perpendicular to each other is placed on the plane of projection, and moved under the given point, representing the place of observation, until by the eye placed above that point and close to it its image is seen to coincide with the intersection of the lines on the glass. Evidently, this intersection is then the projection required on the plane of the mirror, and the corresponding point on the plane of the instrument is easily determined, if desired, by the use of the intersecting lines as lines of reference. In my instrument there is no necessity for determining this point on the plane of the instrument, as the time of disappearance is found by moving the point representing the place of observation, and the disc representing the moon, to successive corresponding positions belonging to successive minutes of time, until the image of the point is occulted by the disc; the time of reapearance is determined in like manner. Instead of the pointed extremity of the rod, may be used a minute perforation in a thin sheet of metal or of pasteboard, through which may be viewed its image in the mirrors. If instead of either of these, were used a polished bead of glass or metal, smaller than the pupil of the eye, the light reflected from it would be seen in the mirror as a star-like point, which by the principles of the projection employed representatives of the star to be octhe culted, and by the interposition of the disc representing the moon, would actually disappear, and again reappear, as in an occultation. The use of the minute perforation gives the best results, as the eye cannot then fail to be in the proper position above the point indicating the place of observa-

I use the same method for adjusting in position a plane which in my instrument represents the plane of the parallel of latitude of the place of observation; this revolves about an axis, to which ought to be parallel the plane of the instrument or the chart, and this parallelism I test by finding, by reflection, the projections of a certain point in three or more widely distant inclined positions of the plane; these projections ought to lie in a right line. This plane ought also to form with the plane of the instrument, or plane of projection, an angle equal to the complement of the declination of the star, and any line in it, perpendicular to the axis of rotation, being taken as radius, will have its projection equal to the sine of the declination. Having a scale of equal parts, for sines, drawn on the plane of the instrument, corresponding to a certain line in the movable plan as radius. I take from a table of natural sines the proper length for the given declination, and placing the intersection of the cross lines on the mirror, to coincide with the proper point in the scale for sines, I rotate the plane about its axis, until the image of the extremity of the radius adopted coincides with the centre of the cross; the plane will then have the proper angle, without requiring an arc divided into degrees and parts, as in Mr. Hill's instrument

Mr. Hill mentions several methods of adjusting the varying relation between the moon's hourly motion and semi-diameter, and decides finally upon a fixed permanent scale, in inches and parts, for hourly motion, and calculates the corresponding values of semi-diameter and parallax, in order to avoid the labour of dividing in every case the moon's hourly motion along its path into minutes of time. I adopt a permanent scale of 10in. for the earth's radius (which fixes moon's semi-diameter also) compute the value on this scale for the hourly motion of moon in her orbit, from the horizontal parallax and hourly motions in R. A. and Dec., for each occultation, and adjust the instrument this varying quantity, by using a scale of equal parts for minutes of time, laid down on an extensible sheet. This sheet is of caoutchouc, and the scale is made variable by extending the sheet, until sixty minutes or one hour on the scale corresponds in length with the computed value of the hourly motion of the moon. Two such scales might be used if the uniformity of the rate of extension of the sheet could not be trusted through. out the required extent of the variation of hourly motion in different parts of the orbit. These scales, made of the vulcanized caoutchous obtainable at the date of the construction of the instrument, have now lost their elasticity and must be re placed before I can again use the instrument.

These expedients are simple, and I make them

known, as the adoption of one or both may add to the efficiency of Mr. Hill's instrument, or similar instruments. I am not aware that any one had proposed them at the time I applied them to my instrument. I have heard that Mr. Adie, of Edinburgh, has proposed something similar to the last to thermometer scales, I believe, but I do not know the date of his proposal, nor whether it has been adopted in the scales of any instruments.

# FLOWER SHOW AT THE CRYSTAL PALACE.

AST Saturday was a grand day at the Crystal

Palace, the occasion being the great Spring Flower Show of the season, which certainly formed a magnificent floral display. The flowers were arranged in double banks along the whole length of the nave, and were sheltered by a new awning which transmitted the sunshine through it in a soft yellow light. The show was divided into twenty-six classes, which were excellently represented. There were also three special prizes given for bouquets, and a large number of competitors, both English and a large number of competitors, both English and foreign, amateurs and professionals, entered into the contest. The result was a collection of beautifully-arranged groups of choice flowers. The show of pelargoniums was splenkid, the foliage and branches of the examples being totally hidden by the blossoms. The stove and greenhouse plants formed the staple of the show, and included some hundreds of the finest specimens. The grounds round Rockhills were thrown open to visitors, and were thronged during great part of the afternoon, every one going to see the great wistaria which covers the front of the villa. This wistaria, which is probably the finest tree of its kind in England, is now in full bloom, and is covered with thousands is now in full bloom, and is covered with thousands of blossoms, from 10in. to 12in. long. The company was one of the most numerous we remember to have seen upon these occasions.

During the afternoon, experiments were being carried out in the tropical department by Mr. J. carried out in the tropical department by Mr. J. Jeffreys, the inventor of a method of preserving meat by the cold process. Mr. Jeffreys proposes to accomplish this by packing the joints in hermetically-sealed boxes, and then freezing the meat contained therein by means of passing them through a "freezing trunk machine," where they will be exposed to a chilling current of from 15deg. to 30deg. Fahr., by means of an ether engine, and then immediately shipped on board a vessel fitted with a special receptacle excluding all outer atmospheric influences, and also subjected during the whole voyage to chilling currents of 10deg., also kept up by a small ether engine. The results of Saturday's experiments were indicative of success, although the lecture room and the ship at sea on a long voyage present very opposite conditions in many respects. However, a committee has been appointed to investigate the whole matter, and to report the result to the food committee of the Society of Arts.

## DYNAMITE.

DYNAMITE.

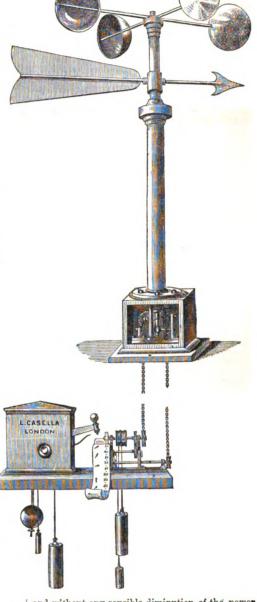

THE following letter upon dynamite as an explosive power, from Mr. W. Hosken, of the Sulphur Mines, Norrtelje, Sweden, dated the 1st instant, appears in the "Mining Journal":—We have been using dynamite here since its introduction by Mr. Nobel. It is well adapted for porous or loose ground, as all miners are well aware how often the charge is lost in cavities or cracks in the ground. Certainly dynamite is a great improvement on powder for that class of ground. In one part of our mines here the lode is occasionally composed of small rounded pieces of rich sulphur, not unlike nuts or marbles, and often there is mixed with the ore, clay, and other decomposed rock, and powder is almost useless in such ground. We use dynamite with considerable advantage, also, in the same ground when it is wet. Looking at the cost of dynamite (2s. per lb.) I do not think it can be generally used in levels or confined places. Our miners here use it with advantage when an opportunity offers in the levels and sinkings. In lime and stone quarries, or large deposits of magnetic iron ore, such as are found in this country, I consider it cheaper than powder. Although not so dangerous as nitroglycerine, it requires careful handling, and a hole or charge that has missed fire should in no case be bored out again.

In consequence of the retirement of Mr. Reverdy Johnson from the United States legation, and his impending return to America, the chair at the forthcoming annual dinner of the Newspaper Press Fund will be filled by the Right Hon. Lord Houghton, president of the Fund. The dinner is appointed to take place at Willis's Rooms on Saturday, June 5.

# EMBOSSING SELF-RECORDING ANEMOMETER.

BY MR. CASELLA.

THIS instrument has been designed for registering the velocity and direction of the wind and the time of its various changes-The general principle of the apparatus is that of Dr. Robinson, of Armagh, in which four hemispherical cups revolve with the pressure of the wind, and give action to most of the other parts. The registering parts of the instrument, however, as well as the vane, are entirely new, and the result of the joint efforts of Mr. Casella, of Hatton-garden, and of Mr. Beckley, the engineer of the Kew Observatory. The force-and-die principle of embossing is the means of registration herein adopted. The paper employed is a narrow strip, wrapped round a small roller, from which it is drawn, and embossed on one edge by the action of the rollers, as shown in the engraving. The rollers are divided to represent miles; they are figured at every ten, and one revolution shows the wind to have travelled fifty miles. The clock raises the small hammer, which falls once in every hour, impressing the other edge of the paper with a small arrow, whose movements are identical with the larger one at the top, and thus shows the exact direction of the wind at the time, as well as its rate of speed during each preceding hour. The paper is of sufficient length to last from four to six weeks without being changed, and the clock may be wound up daily or weekly, as may be desired. The projection below the vane contains metal balls, which firmly support the top, and aid in giving freedom of action. The square box is of cast iron, and contains the stronger portion of the wheelwork; it has holes on the flange for screws or nails, by which means it is easily fixed to the roof of a house, or to a pole placed in a garden, or field, or by the seaside. The chains act on improved rollers, over which they cannot pass without turning them, and are brought into connection with the clockwork and registering parts, placed in a room or box for protection, at any vertical distance from the base, say, from 3ft. to 25ft. In size, the height of the upper part is 39in. from the base of the box, the diameter over the cups is 24in., and its strength and general construction such as to bear the vicissitudes of the severest storm. Where frequent absence is requisite, or in places of difficult access, the little attention required in using this instrument can hardly be overestimated. The action of each one is tested and guaranteed to give the same comparative rate of speed as that of the standard anemometers in use at public observatories.—"Horological Journal." The paper employed is a narrow strip, wrapped round a small roller, from which it

CONTROLLING THE ARMATURES OF ELECTRO-MAGNETIC INDUCTION MACHINES

BY MR. HENRY WILDE.

THIS was a paper on a Property of the Electric Current to Control and Render Synchronous the Rotations of the Armatures of a Number of Electro-magnetic Induction Machines, read before the Manchester Literary and Philosophical Society.

The discovery of the property which the author describes arose out of the efforts which have been made, during the last two years, to reduce the internal heat generated in large electromagnetic machines by the rapid magnetization and demagnetization of the armatures. By constructing the machines of smaller dimensions, this heating was considerably diminished; but an inconvenient residuum of heat still remained when the machines were worked continuously for a long time, such as to render it desirable to adopt some means for abstracting the heat more rapidly.

By means of a current of water, circulating in the hollow brass segments which form part of the magnet-cylinder, Mr. Chas. E. Ryder, the skilful manager at the works of Messrs. Elkington and Co. has happily succeeded in so far reducing this heating as to permit of the machines being worked, for days and nights together, without intermission,

and without any sensible diminution of the power of the current.

The author has already shown, elsewhere, that the current from a small magneto-electric or electro-magnetic machine is sufficient to exite the electro-magnet of a very large machine: and it has been further found, by Mr. G. C. Lowe, that the current from one small machine is sufficient to exite, simultaneously, the electro-magnets of several small machines. In a number of  $3\frac{1}{6}$ -inch machines which have been constructed, under the author's direction, for Messrs. Elkington and Co., for the electro-deposition of copper on a large scale, the currents from two 3½-inch electro-mag-netic machines are made to excite the electro-magnets of twenty similar-sized machines to a degree sufficient to bring out the maximum dynamic effect of each machine.

The electro-magnets of the two 31 inch exciting machines are charged by the current from a small machines are charged by the current from a small magneto-electric machine; but the author has found that nearly as good a result may be obtained from the twenty machines, by dispensing with the small magneto electric machine, and employing the residual magnetism of the two 3½-inch exciting machines, in a manner similar to that described almost simultaneously by Mr. Farmer, Messrs. Varley, Mr. Siemens, and Sir Charles Wheatstone. Wheatstone.

While the subdivision of the materials of one large machine into a number of small ones was attended by several important advantages, yet it

was found necessary to adopt some means to secure the synchronous rotation of the armatures, when the combined direct current from several machines was required.

As the high speed at which the armatures we driven precluded the employment of toothed gearing, the only method which seemed at all feasible for producing the requisite synchronism was to place several machines in a straight line, and connect them together by means of a clutch fixed on the end of each armature spindle. It was while experimenting with a pair of machines so geared together that the author first observed the phenomenon which forms the subject of his

The armatures of these machines were 4in. in diameter, and each of them was coiled with a copper wire conductor, 280ft. long and in in diameter. The currents were taken from the armatures by means of copper brushes rubbing against metal rings connected respectively with the ends of the armature coils, and were therefore in alternate directions for producing the electric light.

The clutch by which the armstures were connected consisted of two iron discs, about 4in. in diameter, having in the face of one, two iron pins which could be guided into two corresponding holes in the face of the other. These discs could be engaged, or disengaged, either when the The relative machines were at rest or in motion. positions of the pins and holes in the discs were such that the armatures might be engaged in reversed positions of half a revolution, when required.

Each of the machines, when making about 2,000 revolutions per minute, was, of itself, capable of producing a very efficient electric light; and when the two armatures were clutched together in such a position that the united positive currents from both machines should proceed from one polar terminal, simultaneously with the united negative currents from the other polar terminal, the sum of the currents from the two machines was obtained. On the other hand, when the armatures were clutched together in the reversed position, without any change being made in the armature connections, no current was produced outside the two machines.

These experiments, besides exhibiting the necessity of synchronous rotation, further showed that the armatures must also occupy the same relative position in the magnet cylinders, in order that the combined currents from the two machines might be obtained. It now occurred to the author to see to what extent the want of synchronism in the armatures would affect the magnitude of the current.

The armatures were therefore unclutched, and allowed to revolve independently of each other, in the same manner as when the attempt was made to take the combined direct current from the commutators. After the alternating current had been transmitted through the electric lamp for some time, it was found that there was no perceptible diminution in the amount of light produced from the carbon points, and that the current would melt, very nearly, the same quantity of iron wire as when the armatures were clutched together. On examining into the circumstances attending this unexpected phenomenon, it was first observed that whenever the machines were stopped, the pins and holes in the respective discs were exactly opposite each other; and that, while the armature were revolving, the two discs could at all times be engaged and disengaged with the greatest facility. Moreover, even when the discs were set (before starting the machine) a quarter, or half a revolu-tion, out of the position in which the maximum amount of current was obtained, it was found that after the aimatures had been revolving for a few moments, the discs resumed their normal positions with respect to each other (as indicated by the action of the clutch); thereby exhibiting, not only the synchronous rotation of the armatures, but also, that the machines contained a principle of self-adjustment to the position in which the maximum effect of the combined current was obtained. It was therefore evident that this property of the current, to maintain the synchronism of the armatures, rendered it unnecessary to employ mechanical gearing of any kind for that purpose.

The author then proceeds to enter into a detailed explanation of the causes which produce the synchronism of the armatures, a summary of which is as follows:-When the armatures happen to be in that position during their revolution in which they are producing the maximum and

minimum amount of current respectively (as must often be the case when there is no synchronism), that current which is at the maximum rushes through the coil which is producing the minimum amount of current,—the effect of this passage of the current from one coil to the other being to accelerate or retard the rotation of the armature (according to the direction of the current) until synchronism is established. On the other hand, the absence of synchronism observed when the direct current was taken from the machines, by means of commutators, is caused by the direction of the currents being coincident with that which they would receive by induction from the electromagnets, and, consequently, opposite to that which tends to impart an accelerating or retarding impulse to the armatures.

The synchronous rotation of the armatures hav ing been secured in the case of the combined alternating currents, it yet remained to obtain the combined direct currents from the two machines. A pair of rings and a commutator were therefore fitted upon one of the armature spindles, which was made sufficiently long for the purpose; and metallic connection was established between the rings of each machine and the commutator on the prolongation of the armsture axis. As the commutator necessarily revolved synchronously with the two armstures, it was found that the combined alternating currents were rectified just as if they had proceeded from only one machine; and were, consequently, available for electro-deposition, or for any other purpose for which a direct current might be required.

Although this property of synchronous rotation has, as yet, been observed only in the case of several pairs and a triple combination, of machines, yet the author sees no reason for supposing that it may not be extended to any number of machines that may be conveniently worked together from the same prime mover. It is necessary, however, to observe that, as the controlling power of the current is only calculated such minute deviations to correct from synchronism as it is beyond the power of mechanical skill to prevent, the driving and driven pulleys should be, respectively, as nearly as possible of the same diameters; as the correction of any considerable difference in the number of the revolutions of the armatures, caused by differences in the diameters of the pulleys, must necessarily be attended by a corresponding diminution of the useful effect of the current outside the machines.

The author concludes his communication by directing attention to an important property of the magneto-electric circuit, which renders the commonly accepted theory by which the generation and propagation of the electric influence in voltaic circuits is explained, inapplicable to those circuits which are entirely metallic. Reference to this property is all the more called for at the present time, as the author finds that a want of acquaintance with it has given rise to no small amount of misconception on the part of several eminent mathematicians and electricians, who have examined his experiments on the electric condition of the earth, and the method by which he has thought proper to estimate the magnitude of powerful induction currents.\*

The intensity of a voltaic current, as represented by the mathematical theory of Ohm, is equal to the electro-motive force divided by the internal resistance of the battery; and from this theory it is inferred than an electro-motor, in order to overcome a great external resistance, must itself possess a correspondingly great internal resistance. A further consequence deduced from this theory is, that the maximum useful effect of a given electro-motor is obtained when the external and internal resistances are equal.

Now, this mode of estimating the magnitude of an electric current does not apply to the circuits on the armatures of the machines invented by the author. Take, for example, the results obtained from the quantity armature of a 10-inch machine. author. The dimensions of the coil of this armature may be represented by a bar of pure copper 67ft. long, and having a sectional area of 1.6 square inches; so that the resistance which this circuit presents to the passage of a current, when compared with that of the liquids in a voltaic battery, is practically null. When the coil is in full action it will melt 15in. of thin iron wire 035in, in diameter, or the same length of in. iron rod with equal certainty; and will electrolize acidulated water in at least 16 voltameters in series: so that the resistance outside the circuit, whether estimated by the 15in. of thin wire melted, or by the number of electro-

lizing cells in series, is more than 100 times greater than that of the coil in which the current is generated.

Moreover, the author has found that whenever a voltaic battery and a magneto-electric machine will melt an equal length of wire, the power which these electro-motors have to overcome external resistance, as measured by the number of voltameters in series, is also equal. And generally the power of an electro-motor (whether voltaic or magneto-electric) to overcome external resistance. is directly proportionate to the length of wire which it will melt.

From a consideration of these results it will be seen that one of the fundamental elements which enters into the theory of Ohm is found wanting when that theory is applied to the estimation of the magnitude of currents generated in circuits entirely metallic. M.M. Jamin and Roger, in a recent number of the "Comptes Rendus" of the Academy of Sciences, have also pointed out the discrepancy here referred to in the application of Ohm's theory to magneto-electric circuits. The author is, however, by no means prepared to admit the correctness of the views advanced by these physicists in their endeavours to reconcile facts observed, with established besides which, other anomalies present themselves when the customary formulæ are applied to magneto-electric circuits, a consideration of which must, as the author affirms, lead ultimately to the enunciation of laws much more general in their application than those with which we are at

#### THE PROJECTED MERSEY TUNNEL AND RAILWAY.\*

#### BY SIR CHARLES FOX.

AS a means of intercommunication between Liverpool and Birkeuhead, a tunnel beneath the sey has been under consideration by leading men on both sides of the river for upwards of thirty-eight years; and when the inconvenience and loss both of time and money which the want of such a means of transit has ever occasioned are considered, it is, in these days of increased facilities, a matter of surprise that, while works of real difficulty have been carried to completion on every side, this obvious want should not have been satisfied. There is but one should not have been satisfied. There is but one opinion as to the importance of intercommunication between Liverpool and Birkenhead, and it being admitted that the great obstacle in the way of its realization is the doubt existing in the public mind as to the cost at which it can be attained, it has been felt that this doubt can never be overcome unless the extense of the given bed in the great of the gr nature of the river-bed is conclusively proved.

When this has been done, I am sure that the construction of a tunnel through the red sandstonerock under the Mersey will be found an easy and rock under the Mersey will be found an easy and inexpensive operation, as, judging from the many similar works which have been executed in this nek during the last forty years (those most analogous having been tunnels of various dimensions carried on at considerable depth below the level of the bottom of the river, with a view of obtaining a more copious supply of water for the town of Liverpool, these hour accepting that have no accepting the second carried and the second carried of the second carried and the second carried and the second carried carried and the second carried carried and the second carried carried carried and the second carried it has been ascertained that in no material can such works be effected at so small a cost as through the very strata now well known to exist in this locality. very strata now well known to exist in this locality, the amorphous nature of the rock rendering it peculiarly advantageous for tunnelling operations. Tunnels have been made at a low price through chalk, as that material is readily excavated; but from its general looseness and its consequent tendency to fall, it is deemed necessary, for the purpose of ensuring safety, to put in brick or stone lining, and this, as compared with red sandstone, which generally requires no such lining, considerably augments the cost; and it must not be forgotten that the sandstone, when excavated from a tunnel in or near a town, is saleable for use as buildtunnel in or near a town, is saleable for use as building material; while chalk, taken from a tunnel, being of no value, is more generally run to spoil.

It would appear that one of the most formidable hindred in the contract of the most formidable in the contract of the most formidable.

hindrances in the way of getting capitalists to embark their money in making tunnels under rivers, of which very many are urgently needed, arises from the disposition which undoubtedly exists to form an unfair comparison between such works and the Thames Tunnel, which, as every one conversant with the circumstances connected with it will know. cost a very large sum, although passing under a river of no considerable breadth. This, however, is no fair criterion upon which to judge of any other case. This tunnel was constructed some forty years case. This tunnel was constructed some within the science of tunnel-making was since, when the science of tunnel-making was since, when it had to be applied little understood, and when it had to be applied upon a very limited scale, without the advantages arising a very limited scale, without the advantages along from many later improvements, and without the ex-tensive experience derived during the last forty years from works of this nature, required in the develop-ment of the railway system all over the world.

(\* Quarterly Journal of Science.)

This makes a comparison deceptive, to say nothing of the Thames Tunnel having to be constructed under all the difficulties of passing, not through London clay, which it would have done had it been placed a few feet deeper, but through the treacherous and loose silt and gravel of the bed of the river Thames, while the tunnel which forms the subject of this paper will pass through solid rock.

Thames, while the tunnel which forms the subject of this paper will pass through solid rock.

To attempt to draw a comparison between this project and the Thames Tunnel is but to show an entire want of acquaintance with the relative circumstances of the two cases, for it must be borne in mind that the Act authorizing the construction of the latter received the Royal Assent on June 24, 1824, more than forty-four years since, and that the tunnel was not opened for passenger traffic till March 25, 1843, having occupied a period of eighteen years and three-quarters in arriving at completion. Were this work now taken in hand by an engineer possessing the experience obtained in an engineer possessing the experience obtained in constructing tunnels since the period above referred to, taking care to place his work deep enough to let it pierce only the London clay (to have done which the present tunnel ought to be 15ft, deeper than it is) no present tunnel ought to be 15ft, deeper than it is) no doubt the entire work could be completed for little more than a tithe of the cost (which was £454,700), and need not certainly occupy a longer period than two years, as is proved by the following facts:—

facts:—
The excavation for the Thames Tunnel commenced in December, 1825, and all went on satisfactorily until May 12, 1827, when, the upper portion of the works protruding above the London clay into the gravel and silt of the bed of the river, the first irruption of water took place, there being then a length of 545ft, of the tunnel constructed, which had bett does into revised of seventeen mostles. been done in a period of seventeen months; so that, had no casualty occurred, and assuming that the rate of progress was not, as it no doubt would have been, augmented by the natural increase which always follows a better knowledge of any work, the ways follows a better knowledge of any work, the whole 1,200ft. would have been completed within three years and two months; and this, be it remembered, would have been the result if made wholly from one end; whereas, with the present increased facilities and knowledge of the operation, it would have been carried on from both sides simultaneously, when, even at the then slow rate of simultaneously, when, even at the then slow rate of progress, the time would be reduced to one year and seven months; so that there can be no doubt that, with present appliances, the work of the tunnel could, with perfect ease, be completed in one year and a quarter; and taking for the shafts and other matters, say, half a year more, the whole could with convenience be accountlished in one year and these. convenience be accomplished in one year and three-

In order to clear up every doubt, I propose, at an estimated cost of £20,000, to drive a heading under the Mersey from shore to shore, a distance of 1,300 yards, and thus not only to prove the practicable nature of the larger and more complete undertaking. but also the future cost, whilst at the same time

but also the future cost, whilst at the same time providing the necessery drainage and ventilation for the permanent works. The first operation will be to sink a shaft on either side of the river, on land belonging to the Mersey Docks Board, to a depth of about 120ft. below the surface.

The shaft on the Liverpool side will, for a depth of say 40ft., pass through made ground, and will then enter, and for the remainder of its length be entirely through the solid rock. That on the Birkenhead side will be in solid rock throughout.

These shafts will be about 10ft. in diameter, and will These shafts will be about 10ft. in diameter, and will These shafts will be about 10ft. in diameter, and will terminate in large sumps for pumping purposes. At each will be erected permanent pumping engines and pumps of sufficient power to deal with the largest quantity of water that is likely to be met with, and which pumps will not only be used during the construction of the works, but be adapted for keeping the main tunnels permanently free from water. Winding engines will also be erected of sufficient power, not only to deal with the material excavated from the heading, but also with that from the tunnel itself.

itself.

The shafts having been sunk to the full depth. The shafts having been sunk to the full depth, and the machinery fixed, the heading will be commenced from either end, and driven much in the same way as an ordinary mining water-level. It will have a very slight rise towards the middle of the river, so as to drain both ways into the shafts. Judging from experience, I expect that, at least four yards lineal a-day will be driven at either end, giving a total of 160 working days, or thereabouts, for the completion of the heading after the shafts are sunk. I have taken much pains to collect evidence as to I have taken much pains to collect evidence as to the nature of the rock through which the heading will pass, and have found everyone conversant with the subject unanimous upon the point. The general result of my inquiries and observations cannot be more forcibly explained than by the following summary of evidence given before the Referees of the House of Commons in 1865.

The late Mr. Thomas Duncan, then engineer to the Liverpool Water Works, stated that he knew well the nature of the rock, which is not very porous. He did not think the quantity of water produced from the rock at Birkenhead and Liverpool would make the tunnel a difficult work of construction, and he did not believe there would be any difficulty in

carrying it through so far as water is concerned. He considered that the "faults" existing in the sandstone rock, and shown on the geological map, were advantageous, as he had cut through many of them (having excavated in the red sandstone at various points over sixty square miles) and had nearly always found them filled up with a species of concerne which water waterly water tight. In a few concrete, which was perfectly water-tight. In a few instances, however, he had found them filled with laminated rock, having a saccharine appearance, and evidently having been subjected to a great heat, and vet water-tight.

yet water-tight.

Mr. James Abernethy, C.E., stated that having been engineer to the Birkenhead Docks, he had large experience of the sandstone rock, and that the rock under the river is good hard red sandstone rock, of the same character as the rock excavated from the Birkenhead Docks, which is a close, compact, strong stone, suitable for building purposes. Mr. John Fowler, C.E., stated that in framing his estimates he had well considered the question of possible faults in the rock, and, on the whole, preferred to have faults of the character known to exist in the red sandstone at Liverpool and Birkenhead, as they, being impervious to water, back up and limit in area the water contained in the interstices of the rock. The faults are filled either with clay or with some The faults are filled either with clay or with some vitreous material. Mr. Fowler further stated that he considered red sandstone at all times the best

he considered red sandstone at all times the best material to construct tunnels through.

Besides the above testimony, there is the further fact that Mr. John Hawkshaw, C.E., F.R.S., proposes to construct a tunnel under the Mersey, near its mouth, where the river is very wide and the character of the rock less certain; and it is therefore evident that engineers of emignee are greed. character of the rock less certain; and it is there-fore evident that engineers of eminence are agreed in considering the work of making a tunnel thoroughly practicable, and that at a moderate cost. As much doubt has been expressed as to the possibility of driving the heading for any such sum as £20,000, I would remark that the trustees have before them a tender from a responsible contractor who is prepared to undertake to complete the work considerably within that amount, finding all considerably within that amount, finding all necessary plant and machinery, and giving approved security to the extent of £5,000.

In driving the heading a boring-rod would, as usual in water bearing strata, be kept ahead of, and at the top of, the work, and thus due notice would at once be given of any unusual feeder of water, should such exist. All ordinary cracks in the sandstone are readily made water-tight by the use of a "feather" readily made water-tight by the use of a "feather" wedge of timber tightly driven into them. If a large crack were met with, containing water (a most unlikely thing, as has been already shown), a lining of iron would be put into the heading and pushed forward, as the excavation proceeded, until the fault was passed. The heading will be circular, and 6ft. in diameter. It will, when completed, be available not only for draining the tunnels, but for telegraphic purposes, and probably also for conveying water from the Welsh lakes to Liverpool, thus avoiding a lengthened detour and most expensive works.

from the Welsh lakes to Liverpool, thus avoiding a lengthened detour and most expensive works.

The heading having been successfully driven, I am confident that there will be no difficulty in letting a contract for a double line of railway under the river Mersey for £100,000, which would, indeed, give a price of £77 per lineal yard of tunnel—the work being through good hard sandstone and thoroughly drained by means of the heading; whereas £60 a lineal yard is a large price for tunnels even through clay, where, of course, heavy lining. even through clay, where, of course, heavy lining, including an invert, is required. The river tunnel being completed, the remaining works necessary to bring the two towns of Liverpool and Birkenhead into complete communication with each other will be of a very ordinary kind, and free from any unusual contingency.

# TO CORRESPONDENTS.

THE MECHANICS MAGAZINE is sent post-free to subscribers of £1 ls. 8d. yearly, or 10s. 10d. half-yearly payable in

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANIC, MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday avening.

Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Advertisements are inserted in the MECHANICS' MAGA-ZINE, at the rate of 6d, per line, or 5d, per line for 13 inser-tions, or 4d; per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertise-ments.

## SAVING LIFE AT SEA.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

-Permit me to suggest the possibility of life often being saved at sea, if there were means of lowering persons into the boats in cases of necessity, by having on board ship a leather belt attached to a chain or rope, so that, with the belt fastened round a woman's waist, she would be lowered over the side by the chain or rope, run out, and have a chance of being picked up by those in the boats. When the being picked up by mose in the boats. Which the best was unbuckled the chain or rope could be wound up—as a measuring tape is. I am only sugesting a last resource, when to jump into a boat is only practicable for sailors—at much risk even for them.—I am, Sir, yours, &c.,

H. B.

# THE LONDON ASSOCIATION OF FOREMEN ENGINEERS.

SIR,—In the brief notice furnished you of the proceedings of the above-named Society at its May meeting, it was stated that Mr. E. J. Reed expressed himself on that occasion as opposed altogether to the patent system. This was certainly the belief of the officer of the Association who wrote that notice; but the disavowal of any such sweeping condemnation of the system by the Chief Constructor himself is sufficient evidence that the statement was inadvertently made. There could, of course, have been no intention to misrepresent that gentleman's remarks; and I am certain that neither he nor any reader of the MECHANICS' MAGAZINE will attribute the circumstance in question to any but its real cause.—I am, Sir, yours, &c.,

JOSEPH NEWTON.

Royal Mint, May 20. SIR.-In the brief notice furnished you of the

Royal Mint, May 20.

SIR.—I regret that any misunderstanding should have arisen as to the meaning of the remarks which fell from the lips of the Chief Constructor of the Navy, while discussing, at a recent meeting of the Association of Foremen Engineers, my paper on Iron Shipbuilding. As those remarks were necessarily summarized for publication, it was scarcely to be expected that the reports given of them in the scientific press would be in all respects exact. My own impression, however, was that Mr. Reed did say that he disapproved of patents generally, as well as of mine in particular. Of course, after that gentleman's explanation, in your last week's issue, it would be uncourteous not to admit myself to have been mistaken on the point in question. I cannot, nevertheless, do other than reassert that I have been somewhat badly treated by the Government in respect of my own patented improvements, in the mode of con-SIR.-I regret that any misunderstanding should what badly treated by the Government in respect of my own patented improvements, in the mode of constructing iron ships. It is an indisputable fact, that I first invented and introduced the system of connecting the keel and keelson with the stem and sternpost, which is now adopted in the building of every war ship of the British navy. Equally true is it, that my improvements have produced no advantages to myself, in a pecuniary sense, whilst, on the contrary, I have sustained heavy losses in defending what I considered to be my patent rights. That Mr. Reed would be the very last ment of imputation and residence in the ments of considered to be my patent rights. That Mr. Reed would be the very last man to dispute the merits of an invention or an inventor on other than conscienan invention or an inventor on other than conscientious grounds, I am assured; but, I think, in my case, he has overlooked some of the facts, and, without wishing it, has done me injustice. The peculiar mode of affixing stem and sternpost to keel and keelson, which is the characteristic of my patent, is what I claim credit for, and not the mere fact of making that connection by some means or other. It is not for me, on the present occasion, to trespass further on your space, but I trust you may find a corner for this brief rejoinder.—Iam, Sir, yours, &c.

JAMBS RAE.

27, Fenchurch-street, May 19.

# Habal, Military, and Gunnery Items

On the 26th ult., the steamer "St. Elmo" exploded her boilers in Mobile Bay, Alabama, killing one of her officers and seriously injuring six other persons.

A BOARD of officers has been in session at the Washington Navy-yard several weeks past, for the purpose of selecting a breech-loading rifle to be adopted in the U.S. navy.

THE National Life-boat Institution has just received from the executors of the late Mr. Thomas Brown, formerly of the firm of Messrs. Longman and Co., a legacy of £500, duty free.

Mr. ROBERT WILCOX, of Melbourne, has prepared a model illustrative of a method invented by himself for using submerged guns for purposes of naval warfare, by running out a gun so as to project for a distance of 12ft. from the vessel's side.

WE hear that a contrivance by which the true magnetic line will be indicated in every latitude uninfluenced by local causes, and which will prevent or obviate the variation of the compass, has been discovered at Graff Reinet. The discoverer is on his way to England to secure the patent.

THE "Somersetshire," gold ship, which has just arrived in England, held on her outward voyage a bazaar in aid of the Belvedere Institution, realising ten guineas; and on her homeward passage, on the 1st of February, a second bazaar, in aid of the Mer-chant Seamen's Orphan Asylum, realized £48 4s. 2d.

THE board of which Rear-Admiral Goldsborough is president, now in session at the Brooklyn Navy-yard, has a work before it of great magnitude. It is no less than to discover the errors of the old Steam Bureau, and to recommend plans for remedying them.

The new steamship "America," of the Pacific mail line, will sail from New York on a trip round the world, on or about the 1st of June, and will return to New York by the middle of November. Fare, 1,230 dollars, with the privilege of living on board while in port. The burden of the "America" exceeds 4,000 tons.

THE Aucient Order of Foresters has forwarded an additional contribution of £440 to the National Life-boat Institution on account of their second life-boat, which is to be launched in Sunderland in the beginning of August next, in the presence of some thousands of Foresters, who are to assemble on the occasion from all parts of the north of England.

FUETHER trials of the new bronze field gun for India were made on Monday and Tuesday last at Shoeburyness, with a continuation of very satisfactory results. The light iron carriages are perfect in their endurance. Case shot was also fired from the light Abyssinian steel gun at 200 yards, the effects of the bullets being severe upon the wood targets.

At the Washington Navy-yard a large number of At the Washington Navy-yard a large number of workmen are busily engaged in preparing the monitor "Saugus" for sea. A full and thorough cleansing and repairing has been given her. As soon as the "Saugus" leaves, the monitor "Mahopac" will be hauled in and completely overhauled and repaired, and prepared for sea. The purpose of the Department is to save the monitors from going to decay, as they are likely to do if left as they are.

An estimate was recently obtained by a New York shipping firm, for the building of a first-class iron sailing vessel in this country, but it now appears that the vessel is to be built in New York, more that the vessel is to be built in New York, more favourable terms having been obtained there, and that only the wire rigging, anchors, and chain cables, are to be supplied from England. This, we understand, will be the first American built iron sailing vessel to cross the Atlantic.

THE new King of Siam is busied with the organi-THE new King of Siam is busied with the organization of his army, and has named as the commander in chief of the Siamese troops a Frenchman, M. Ganier d'Abin, who served formerly in the national Polish army with the rank of colonel, and particularly distinguished himself during the insurrection of 1863-1864. The Siamese infantry is to be organized on the French system, and will comprise divisions, brigades, regiments, and battalions, with new arms. new arms.

THE departure of the German expedition to the North Pole is fixed for June 7. The "Germania" and the steamer "Harmonia" will proceed direct to the Island Jan-Mazen, and then go northward, and endeavour to discover an opening in the ice between the 74th and 76th degrees of latitude. If by the end of August the expedition should not have succeeded, the vessels will go and pass the winter either at Spitzbergen or at Gilsland, and resume the enterprise in 1870.

CER eminent name must be added to the long and Admiral Prince Alexander Menschikoff, of and Admiral Prince Alexander Menschikoff, of Crimean celebrity, died on the 1st instant, and was buried on the 6th with great pomp, the Emperor of Russia and several members of the Imperial family being present at the funeral. The deceased was eighty-two years of age, and had lived in retirement since the stirring scenes of the Crimean war, in which he was one of the chief actors.

passengers. Fifty have been burnt to death or drowned, and as many more injured. There was a drowned, and as many more injured. There was a large number of United States soldiers on board, who were coming down from the various military posts among the Indian tribes from the Upper Missouri.

Colonel George Gawler, K.H., died recently at Southsea, aged seventy-three. The deceased officer entered the army October 4, 1810, and served in the Peninsular with the 52nd Regiment, from November, 1811, until the end of that war in 1814, including the siege and assault of Badajoz, battles of Vittoria, Pass of Vera, the Nivelle, the Nieve, Orthes, and Toulouse, besides various minor affairs. He served also in the campaign of 1815, and was present at the battle of Waterloo. Colonel Gawler was wounded below the right knee, by a musket shot, at the storming of Badajoz, and in the neck, by a musket shot, at San Munos. He had received the war medal with seven clasps. war medal with seven clasps.

THE "Victoria and Albert," royal yacht, which has THE "Victoria and Albert," royal yacht, which has been in dock for some months, undergoing extensive alterations and repairs, is progressing rapidly, a great alteration having been made in her appearance within the last three weeks. The inner coats of planking over her frame are entirely completed, and the outside planking is nearly finished, while the works on board are also being pushed forward, so that she may be ready for engine work at an early date, when she will be removed into the steam basin, the dock being, it is understood, required for a new turret ship (the "Devastation") which is to be built there. The "Victoria and Albert" will not be ready for ese until the summer of next year. for sea until the summer of next year.

ANOTHER veteran of the "Great War" has departed. Admiral Bateman Dashwood died suddenly at Geneva on the 9th inst., in the 80th year of his at Geneva on the 9th inst., in the 80th year of his age. The gallant officer entered the service in 1799, and served uninterruptedly till the peace of 1815. He was a midshipman in the "Defiance" at the battle of Copenhagen, under Lord Nelson. In 1811, he was first lieutenant of the "Active," then commanded by the late Sir James Gordon, G.C.B., and when that officer fought and took the French frigate "Pomone," after a desperate contest. When Sir James had his leg shattered by a cannon shot, Lieut. Dashwood took the command of the "Active" until he himself lost his arm, and the French ship finally struck to the third lieutenant. third lieutenant.

# Miscellanea.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending May 15, was 3,534. Total number since the opening of the Museum, free daily (May 12, 1858). 1,563,870.

THE name of the thimble is said to have been derived from 'thumbell,' having been first worn on the thumb, as the sailor's thimble still is. It is of Dutch invention, and was brought to England about the year 1605, by John Lofting, who commenced its manufacture at Islington.

THE Fairbairn Engineering Company have now in hand, and will be shortly ready for exhibition, a set of 60-horse engines, constructed upon an entirely new principle, which, besides possessing other important advantages, will consume probably less than half the quantity of coals required by the best steam engines at present in use.

Advices from the south of France relate that an enormous amount of damage has been done by the hall in the department of the Aude, twenty-five communes having been devastated, with a loss of nearly a million and a-half of francs. The arrondissement of Muret, near Toulouse, has also been laid waste to an extent of five kilometres.

THE council of the Society of Arts propose shortly to appoint a day for discussing any practical measures for improving the cab system in the metropolis. Any person who may desire to submit proposals for discussion are requested to communicate them in writing to the secretary of the Society of Arts, John-street, Adelphi, on or before Saturday, the 29th inst.

ONLY 106,000dols. have been appropriated by Congress this year for the survey of the great lakes on the northern frontier of the United States. This amount is much below the appropriation for 1868. It is proposed, however, to finish the survey of Lake Superior, and to continue the experiments to ascertain the supply and outflow of the water, by gauging the short straits or rivers connecting the lakes.

THE annual exhibition of the Bath and West of England and Southern Counties Agricultural Association, to be held at Southampton, commencing on since the stirring scenes of the Crimean war, in which he was one of the chief actors.

On the morning of April 24 the steamer "Uselda," while coming down the Missouri river, struck a snag near Sioux City, and began to sink. As she was gradually sinking, the water rose around the boilers, and they suddenly exploded, shattering the boat to pieces, and killing and wounding a large number of

THE total amount of money paid into the Inland Revenue in Great Britain and Ireland for the duty on fire insurances during the year ended December 25, 1868, was £964,514 6s. 6d. The sums insured by the various offices on farming stock—exempt from duty—in the same period amounted to £75,419,003.

The value of the steam engines exported in the first three months of this year was £294,478, as compared with £290,796 in the corresponding quarter of 1868, and £397,833 in the corresponding quarter of 1867. The demand for our steam engines in British India has considerably fallen off, probably because forwar learners, and the sentent of the sentent fewer locomotives are now required to be sent out for the great Indian railway lines.

THE Emperor Napoleon is having a villa built at Rome on the Palatine Hill. The ground has been bought from the King of Naples for a sum of 50,000 francs, and on the spot are found the remains of the Palace of the Cosars. Although the new erections are nearly terminated, excavations are still carried on under the direction of M. Rosa (a descendent of Salvator) who is the conservator of the prime. Salvator), who is the conservator of the ruins.

AT a recent Court of Common Council it was re-Ara recent Court of Common Council was re-ported that the new Blackfriars Bridge would be ready for opening in July next, and the Improve-ment Committee was requested to report as to the public ceremonial to be adopted to signalize the event. A suggestion that the Holborn Valley Via-duct should be opened on the same day was referred back to the committee. back to the committee.

THE Cosumnes Bridge, on the Western Pacific, will be a Howe truss, 600ft. long, and the trestle work immediately connected with it will be 800ft. long, while another piece of trestle work over a slough through which the waters of the Cosumnes run in flood time, will be about 300ft long, thus making an opening for the waters of the river of 1.700ft.

THE number of visitors to the South Kensington THE number of visitors to the South Kensugton Museum during the week ending May 15, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 11,967; Meyrick and other galleries, 2,061; on Wednesday, Thursday, and Friday (admission 6d.) from 10 a.m. till 6 p.m., 2,624: Meyrick and other galleries, 205; total, 16,857. Average of corresponding week in former years, 11,206. Total from opening of Museum, 8,424,336.

On the 1st of June next, the tariff on Atlantic cable On the 1st of June next, the tariff on Atlantic caole messages will be reduced from £37s. 6d. for ten works, and 6s. 9d. for each additional word, to £2 for ten words, charging for address and signature, and 4s. for each additional word. An important reduction will also be made for newspaper press messages, and all political and general news will be conveyed from either side of the Atlantic at half rates. This will predice the press messages from 6s. 9d to 2s. practically reduce press messages from 6s. 9d. to 2s.

YESTERDAY week, at the weekly meeting of the Mersey Docks and Harbour Board, a letter was read from Messrs. William Low and George Thomas, civil engineers, proposing to connect the Lancashire and iverpool and Birkenhead. They propose to accomplish this by a suspension bridge of three spans, the centre being 1,800ft. in length, and the others 960ft. each, the bridge to be 140ft. above high-water mark. Estimated cost, £1,750,000.

apid strides every year, not only in quantity but in quality. From the report of the North German 

The Direction of the State Domain has during the last few days been selling by auction, at Paris, property abandoned in the railway stations or carriages. Nothing can be more curious than this collection of proofs of forgetfulness or negligence, comprising firearms, pipes, shoes, chignons, perfumes, jewellery, hardware, hats, bonnets, caps, shawls, mantles, &c. An immense number of travelling bags had been left behind, and the books forgotton would form a large library; there is also an enormous quantity of wines, liquors, and divers kinds of merchandise. liquors, and divers kinds of merchandise.

THE Royal Horticultural Society's last meeting was remarkable for many beautiful objects exhibited. Amongst the most prominent was a rhododendron named Beauty, from Mr. Standish; the Golden Osk, from Messrs. Lee, was also remarkable, and promises to be a great acquisition. A cut flower of Rhododendron Falconerii, grown in the open air in Mr. Lloyd Wynne's garden at Coed Coch, in Denbighshire, was also much admired. Mr. Wilson Saunders, F.R.S., presided, and the following candidates were elected follows.

THE French Atlantic cable is now completed with the exception of about 170 miles, and the whole will be ready in the course of noxt week. It is arranged, therefore, that the "Great Eastern," with the attendtherefore, that the "Great Eastern," with the attendant vessels, shall leave Sheerness on June 10, calling to coal at Portland, whence she will proceed to Brest, where she is expected to arrive on the 20th. From Brest she will immediately start for St. Pierre, off Newfoundland, while two other ships will sail for St. Pierre direct to lay the portion of the line between St. Pierre and Duxbury, Massachusetts. The land line from Duxbury to New York is already in course of construction. in course of construction.

On Tuesday evening, the 25th inst., Mr. Charles Hutton Gregory, the president of the Institution of Civil Engineers, will receive the members at his annual conversazione, to which he has invited all the leading celebrities of the day, many of whom may be expected to be present. During the session just concluded there have been added to the registry of this Institution one honorary member (H.I.M. Napoleon III., Emperor of the French, 30 members, and 82 associates, while the council have admitted 31 students. The numbers of the several classes now on the books are 17 honorary members, 664 members, 934 associates, and 143 students, or a total of 1,758 of all classes. On Tuesday evening, the 25th inst., Mr. Charles of 1.758 of all classes.

SIR CHARLES WENTWORTH DILKE died suddenly on the 10th inst., at St. Petersburgh, to which capital he had repaired as the representative of capital he had repaired as the representative of England at the forthcoming exhibition of the Russian Horticultural Societies. The deceased baronet was born on February 18, 1810, and was educated at Westminster, and at Trinity Hall, Cambridge. For a short time he studied law; but afterwards gave up his leisure to the affairs of three or four learned societies. He took a prominent part in the Society of Arts, of which he was for some years chairman of the council, and also in the Royal Horticultural Society, which owes no little of its public prosperity to his exertions. He was one of the first promoters to his exertions. He was one of the first promoters of the Great Exhibition of 1851, and acted as one of the executive committee.

# Patents for Inbentions.

### ABRIDGED SPECIFICATIONS OF PATENTS.

TATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES-3344, 3371, 3376
BUILDINGS AND BUILDING MATERIALS-3331, 3339, 3368, 2374

CHEMISTEY AND PHOTOGRAPHY—None.
CULTIVATION OF THE SOIL, including agricultural implements and machines.—None.

3316 W. Brown, Smethwick. Rolling metals. Dated October 20, 1868.

This refers to letters patent, dated September 12, 1867 (No. 2588). In the specification of those letters patent the inventor described two sets of parallel rolls driven at different velocities, the bar to be rolled being passed directly from one set to the other set, the second set moving at a rate greater than that of the first set, so as to receive the lengthened bar at the additional speed which its elongation requires. He finds that three or more sets of rolls similarly arranged and driven may be used with advantage, and one part of the present invention consists in the use of three or more sets of parallel rolls driven at different velocities. Another part of the present invention consists of an arrangement for driving the strand or roducing rolls. Instead of the toothed wheel, described and represented in the specification before referred to, the inventor employs a large toothed wheel on the shaft of the lower roll of the first pair of rolls. This toothed wheel takes into a pinion on the shaft of the middle roll of the second set of three rolls, and the last described pinion takes into a pinion on the shaft of the lower roll of the next pair of rolls, and so on through the whole series. The invention is applicable to the rolling of metals in general, but is especially applicable to the rolling of from and steel and copper and alloys of copper.—Patent completed.

3317 A. S. PATERSON, Cincinnati, U.S.A. Bool heels. ated October 30, 1868.

3317 A. S. PATERSON, Cincinnati, U.S.A. Boot heels. Dated October 30, 1868.
This consists in making heels of vulcanized rubber combined with two metallic plates, which are screw-capped to receive the point of a screw entered from the inside of the boot or shoe for fixing the heel thereto. The metallic plates are shaped in any convenient way to touch at one or more points, but with space otherwise for the rubber to extend between them. The rubber is cured with the two plates in it, these being riveted together and the rubber pressed into the mould with the plates in position, so as to solidly fill up the space between the plates as well as to occupy the remainder of the heel-shaped cavity.—Patent abandoned.

-Patent abandoned.

3318 W. COLLINS, jun., Glasgow. Separating paper.
Dated October 30, 1868.

The object is the automatic separation of paper or other sheets from a pile, and the feeding or removing of the sheets for various purposes, such as gumming or folding, to make envelopes, or embossing or printing, and the invention consists principally in employing a sucking mouthplece of a peculiar conformation, and in applying it so as to lift only one edge or corner of the sheet, and also in limiting the action of the sucker to mere lifting, gripping fingers. rollers, or equivalent details being used to remove the sheet after it is lifted.—Patent completed.

3319 G. WRIGHT. Sheffield. Printing presss. Dated

3319 G. WRIGHT, Sheffield. Printing presses. October 30, 1868.

October 30, 1868.

This consists principally of an improved printing or embossing press, which is worked by means of a lever with eccentric action on a piston, at the bottom of which is a pad of vulcanized india-rubber or other suitable material. Beneath this piston is a metal bed, on the face of which are dove-tailed slides to receive the dies, which, being made of a size to move freely therein, may be changed at will. At the back of this bed (in a rack in which are cut diagonal slots) are placed one or more rollers of suitable thickness, on which is wound carbonized paper or other material of such colour as may be desired the slots permitting the rollers to be at once changed, and other coloured rollers substituted.—Patent abandoned.

3320 G. ALLIX, Southampton. Raising and lowering boats Dated October 30, 1868.

3320 G. ALLIX, Southampton. Raising and lowering boats. Dated October 30, 1868.

This consists, first, in an improved arrangement of apparatus for raising ships' boats from and lowering them into the water; and, second, in improved arrangements for disengaging the boats when so lowered. From the davit heads brackets or frames are suspended, in which bearings are formed for a spar, on the ends of which are barrels to receive the hoisting and lowering chains or ropes. On one end of the spar is a toothed wheel driven by a pinion on the same axis as another wheel driven by another pinion, which last pinion is on the axle of a driving pulley, round which a rope or parbuckle is wound. By hauling on this parbuckle the spar is caused to rotate, wind up the hoisting chains, and thereby raise the boat. By leaving the parbuckle free to wind on its pulley, the weight of the boat causes the spar to rotate in the contrary direction, and thereby to let the chains run out and lower the boat. The arrangement for disengaging the boat when it reaches the water is a self-acting arrangement, and is intended to prevent the hook at one end of the boat boat touches the water first. It consists in the employment of two counterbalanced hooks, one at each end, rigidly fixed to a fore and aft bar, to which the hoisting and lowering chains are attached. These hooks take into eye or ring bolts in the boat, as usual, and when the weight or strain is taken off the chains by the boat touching the water the counterbalanced hooks turn simultaneously with the fore and aft bar, and become released from the bolts.—Patent abandoned.

3321 S. Sharrock, Liverpool. Lamp posts. Dated October 30, 1868.

3321 S. SHARROCK, Liverpool. Lamp posts. Dated October 30, 1868.

The inventor employs a taper formed of a sheet or sheets of wrought iron, bent round and with the edges riveted together along the side of the tube. He also places stays or hoops in these posts to strengthen them at points where they would be liable to collapse. The post at its lower end may be inserted directly into the ground or into socket of east iron, or an ornamental base, for the post may be formed of cast iron; this base rests on the surface of the ground, and the post passes through it. The base serves to steady the post, as well as to give it a more ornamental appearance. The top of the post receives a socket which carries the lanthorn, or the lanthorn may be attached in any other way.—Patent completed.

3322 W. E. DANDO, Manchester. Mourning hats. Dated

October 30, 1868.

This consists in covering the upper portion of the body of the hat with silk or any such material as may be commonly used for hats, and covering the lower portion with cloth or any such suitable material as may be made to represent a mourning band, so that the cloth forms a portion of the hat itself, being fixed direct to the body of the hat during the process of manufacture.—Patent abandoned.

3323 R. IRVINE, Leith, N.B. Alcoholic liquors. Dated October 30, 1868.

This relates to the economizing and utilizing of those refuse products containing starch, which result from the process of brewing and distilling, and has for its object the production of sugar from such refuse products, to be afterwards converted into alcohol by fermentation. In carrying out his invention, the inventor takes any of the before mentioned refuse products and adds thereto water acidulated with sulphuric acid, or such of its saits as have an acid reaction, which are most suitable for the purpose. The proportion in which he employse either the acid or the acid salts will vary according to the amount of starchy matter contained in the refuse products, the object being to convert the same into starch sugar, or partly into starch sugar, and partly into dextrine. This saccharine material the luventor designates, for the sake of convenience, "matt extract," from its similarity in proporties to that substance as obtained from malt.—Patent abandoned.

3324 J. Bronner, Frankfort-on-the-Maine. Gas shades.

Frankfort-on-the-Maine. Gas shades

3324 J. BRONNER, Frankfort-on-the-Maine. Gas thades. Dated October 31, 1868.
This consists in so constructing a shade that when applied to a gaslight, the jet will burn at a certain regulated distance from a vertical or nearly vertical plane, the expansion of the flame being parallel therewith. The effect of this construction and arrangement is that this flat vertical side of the shade becoming heated, a perpendicular current of hot air is produced, steadying the flame,

and doing away with the wavering so injurious to the eye, and to which the fiame from batswing and fishtail burners is specially subject.—Patent completed.

and doing away with the wavering so injurious to the eye, and to which the flame from batswing and fishtail burners is specially subject.—Patent completed.

325 W. E. BATS and T. Dond, Northwich. Cracking nuts. Dated October 31, 1868.

This relates, first, to improved machinery employed principally for the purpose of cracking palm nuts in order to remove the shells previously to their being submitted to the press for extracting the oil. Second, to improved machinery for separating the kernels of the nuts or fruits from the husks or shells after having been cracked. The inventors construct an ordinary centrifugal fan or pump consisting of a disc with blades, fans, or leaves attached to its periphery revolving round an axis in a barrel or case of sheet iron or other metal. At the points where the water is conducted into the ordinary centrifugal pump, they introduce the nuts or other fruits required to be broken, which for this purpose are contained in a hopper placed above the machine. The blades, fans, or leaves exactly fill the interior of the barrel or case, as, if any space were left, the nuts would accumulate and choke the machine. The disc and blades are then caused, by steam or other motive power, to revolve at a great speed. The blast or current of air generated by the rapid revolution of the disc and blades, and, aided by the centrifugal force, also generated thereby causes the nuts or other fruits to fly off with great force at a tangent slong a discharge or exit pipe. A perpendicular or slightly inclined target or shield of metal or wood is erected at a convenient distance from the fan, and in front of the mouth of the exit pipe. The space between this target and the mouth of the exit pipe is boxed in to prevent the broken shells and nuts from flying about. The nuts or other fruits to be cracked are driven with great force against this target, and are consequently broken, falling down immediately in front of it into a convenient receptacle. The second part of the into a form the husks or shells after b

centringal force generated by the revolutions, and endearour to escape through the apertures or perforations.—
Patent completed.

3326 A. M. CLAEK, Chancery-lane. Seeing machines.

(A communication). Dated October 31, 1868.

This consists, first, in acting on one or more of the
principal parts of a sewing machine in a direct manner by
means of a receiver or receivers of the electro-motive
power which is transmitted from any suitable battery.
Second, in making said receivers independent or acting in
combination as desired, and according to the arrangement of the machine used. Third, in dispensing in this
manner with the friction inherent where the motion is
transmitted by gearing. Fourth, in simplifying and reducing the cost of the machine. Fifth, in combining in
one machine both the receiver and the sewing mechanism.
The power of the receiver is applied direct to the sewing
mechanism, viz., the needle carrier, hook or shuttle wheel
or other feeder, thus producing a sewing machine of
essentially novel arrangement, as regards the mode of
operating the working parts. The parts being thus
arranged, a maximum effect is obtained from the electric
receivers with a given amount of fuid.—Patent completed.

3227 J. Langford, Birmingham. Teapot handles.

receivers with a given amount of nuid.—Fatent completed.
3327 J. LANGFORD, Birmingham. Teapot handles.
Dated October 31, 1868.
Rings of porcelain, or other imperfect conductors of heat, are inserted between the ends of the handle and the teapot or other vessel, or between the part of the handle which it is wished to protect from heat and the other part to which it is wished to protect from heat and the other part to which it is joined.—Patent abandoned.

part to which it is joined.—Patent abandoned.

3328 B. DICKINSON, Hope Town, India. Propelling essels. Dated October 31, 1868.

The inventor employs trough plates or channels, running longitudinally, to prevent the lateral diffusion of the water as it issues from the jet or discharge pipe at the bottom or sides of the vessel, such apparatus being placed, in every case, below the water line, and forming placed, in every case, below the water line, and forming placed, in every case, below the water line, and forming placed, in every case, below the water line, and forming heat rough plates or channels may be either straight in their vertical depth, or curved or angled, so as to regulate more perfectly the direction of the flow and discharge of water. In some cases, also, instead of being parallel to one another, the trough plates or channels are made to angle outwards towards the stern of the vessel, in order to admit of a freer course and to reduce the friction. The openings for the emission of the water may be placed either directly under the centre line of the vessel, or on the other side of the keel.—Patent completed.

3329 S. A. VARLEY, Holloway. Generating static elec-

3329 S. A. VARLEY, Holloway. Generating static elec-ricity. Dated October 31, 1868.

3329 S. A. Varley, Holloway. Generating static electricity. Dated October 31, 1868.

This consists in so treating glass tubes or cylinders as to prevent the condensation of moisture on the inner surface, and also in so constructing them as to obtain a much greater exciting surface in a given space than with the ordinary construction of frictional electrical machine, when he desires to develope large quantities of electricity, of a series of glass tubes; into these tubes he pours hot melting cement, which he prefers to consist of 32 parts Stockholm pitch, 16 parts black resin, and 4 parts of becawax. The object desired is to cost the inner surface of the glass with an electric which does not attract moisture. Sulphur or parafin may, in some cases, be substituted for the cement above described. These tubes are mounted on bearings, and arranged in one plane, and are made to revolve by means of a band passing round pulleys attached to the glass tubes and driven by a multiplying wheel, or by any other suitable means. Bubbers coated with amalgam, similar to those used for the ordinary frictional electrical machine, pressed against the one side of the revolving glass tubes, and collecting points in metallic connection with an insulated conductor are arranged on the opposite side over the glass tubes.—Patent abandoned

3330 A. Muuso and W. B. Adamson, Glasgow. Manactive of tools. Dated October 31, 1868.

Taus relates, in the first place, to the employment of

creosote or hydrocarbons for the purpose of making tools and other articles composed of iron, steel, or metallic alloys, much harder and more thoroughly tempered than hitherto. The tools or other articles to be hardened or tempered are heated to the necessary temperature and cooled by immersion in the creosote or hydrocarbon, and to further increase the hardness or temper of the tools, or other articles, carbon, or other indurating substance, may be mixed with it. The invention relates, in the second place, to the manufacture of iron, steel, and metallic alloys or tools, or other articles composed of iron, steel, or metallic alloys, and it consists in treating the iron, steel, or metallic alloys are melted and rendered dense and hard by being cast in chills, the chilled iron, steel, or metallic alloys are melted and recast into chills, the result being the production of a much harder, denser, and more durable material than hitherto obtained.—Patent abandoned.

3331 S. Ault, Bridgtown. Trowels. Dated November 2.

1868.

The inventor makes the holder of two uprights or tangs, between which a scrow pin or rod is secured near their tops. This pin or rod carries the wooden handle, by which the holder is grasped while using the trowel. On the bottom ends of the uprights, and made in one piece therewith, is a dovetail or connecting plate, which has a taper figure that is wider at one end than at the other. On the upper side of the steel plate of the trowel, a hollow dovetail or seat is fixed of a size and figure suited to receive the taper dovetail on the bottom of the holder.—Patent completed.

8332 J. LODGE, Yeadon. Looms. Dated November 2,

1868.
This consists, first, in connecting each weft fork rod the knocking-off lever by a swivel or joint, and applying a bracket to the breast beam to guide the fork straight or in a right line when acted upon. Second, in the application of a spring "brig" or bridge to each weft, fork, race, or recess in the batten or "going part" of looms where wheel shuttles are used, which "brigs" are lifted even with the surface of the shuttle race, by suitably formed incline plates, fixed to the loom end, so that the said fork, races, or gaps in the batten or shuttle race, are filled up at the time when the shuttle is passing over, and as the "going part" moves forward towards the cloth, the inclines cease to act on the "brigs," and the springs act to sink them into the recesses to pass under the forks.—Patent abandoned.

8333 F. T. LABITTE, Paris. Advertising. Dated Novem

ber 2, 1868. This consists in applying addresses, advertisements, notice, and illustrations, to articles of various kinds and forms, made of ceramic materials, glass, and crystal, either by drawing or painting, by caligraphy printing, autography, or lithography, or by photography, or engraving, or by any other like process.— Patent abandoned.

other like process.—Tatent abandoned.

3334 J. Dannatt and T. S. Turnbull, Sunderland, Safety garment. Dated November 2, 1868.

This consists principally in an inside double lining, which is applied to the jacket or other garment, forming an air chamber. It is made of india-rubber or other air-proof material, and is provided with a flexible tube, having a mouthpiece with a valve opening inwards, by means of which the wearer can at any time inflated it when required. After the jacket or other garment has been inflated, the air is kept inside the same, and is prevented from escaping by turning a screw attached to the mouthpiece. A broad hem runs round the bottom, breast, and arm holes (of the jacket, for example), for attaching it to the outside and inside lining of the garment without perforating the air chamber.—Patent completed.

3335 J. VAVASSUR. Southwark. Discharging ordnance.

3335 J. VAVASSEUR, Southwark. Discharging ordnance. Dated November 2, 1868. The inventor introduces into the outer end of the vent.

the inventor introduces into the outer end of the vent, which is suitably chambered to receive a capsule like the case of a cartridge for a breech-loading rifle. This capsule is provided with a percussion priming, and is loaded with a charge of gunpowder or similar explosive material sufficient to produce the volume of fiame required.—Patent completed.

33?6 J. H. BERTIE, Nottingham. Lace. Dated November 2, 1868.
In order to obtain a net like the ground of hand-made.

, 1868.
order to obtain a net like the ground of hand-made In order to obtain a net like the ground of hand-made blond, the inventor employs a complement of threads consisting of one warp thread to each bobbin thread, and he uses four of these threads, that is to say, two warp threads and two bobbin threads, to produce each pillar of the ground net. This is not in itself new, but according to the invention the crosses are made from pillar to pillar in such next, having two bobbin threads and two warp threads in each pillar.—Patent completed.

threads in each pillar.—Patent completed.

3337 J. Moorr, Moston. Woren fabrics. Dated November 3, 1868.

This relates to an improved manner and method of laying the weft in the shed, and consists, first, in laying the weft more openly in the shed by preventing the different folds from twisting round each other, and also by preventing one fold from riding on the other. Second, in the increased facility afforded of mixing the weft, and also of introducing a change in the nature or kind of weft. To accomplish this it has bitherto required the use of the pick and pick loom. The means adapted for this purpose consist in the use of two shuttles, the shooting of two picks from each in succession, and in putting two picks, as before, into the same shed; but in starting, an odd pick only is to be used, and this is accomplished by removing the bottom shuttle from its box and placing it at the single end of the lay, and then picking it back into its proper box; the boxes which were raised to admit of this are then dropped, and the top shuttle is passed through the same shed in the body of the warp as that in which the previous or bottom shuttle was passed.—Patent abandoned.

doned.

3338 L. Berenger, Paris. Ironing and pressing. Dated November 8, 1868.

The inventor suspends the iron to be used on a frame carrying rollers or wheels, which travels on rails or a platform, fixed above the cloth or material to be ironed or pressed. He suspends the iron to this frame by a screw or other mechanical appliance, which serves to lift the iron from the material to be operated upon, and to give any desired pressure by means of the iron upon the said material.—Patent completed.

2320 1 and R. MAIN Glasgow. Iron shell. Dated No.

3339 J. and B. MAIN, Glasgow. Iron sheds. Dated No ember 3, 1868.

This consists in arranging a light roofing of corrugated

or other suitable sheet iron so that it can be adjusted at various heights, to suit the quantity of produce stacked or placed under it.—Patent completed.

3340 E. BARTON, Robinson-road, N.E. Scarves. Dated

3340 E. BARTON, Robinson-road, N.E. Scarves. Dated November 3, 1868.

This consists in a plain broad flap of any suitable material, and of one piece, passing down in front of the shirt, the lower end being, by preference, made much narrower than the upper part, which flap is secured round the neck by means of a band attached thereto.—Patent aban loned.

than the upper part, which dap is secured found the neck by means of a band attached thereto.—Patent aban found.

3341 S. Schuman, Glasgow. Utilizing fecal matters, Dated November 3, 1868.
In carrying this invention into operation with the existing system of water-closet, the pipe or shaft leading from the pan of the closet is contracted at its lower end and connected to a porous or perforated receptacle, formed, by preference, of straw basketwork, felted or other similar substance, knitted or woven, the lower part of which is in communication with a lower receptacle or reservoir. As soon as the fecal matter and water are discharged from the closet, these fall into the porous or perforated receptacle, and the liquids, water, and urin' drain through into the receptacle below. The lower receptacle is connected by a pipe with a large district reservoir, into which the urine, water, and all matter mixed with the fluids are discharged, and in which they are evaporated at the natural temperature, or by artificial heat, and the product separated from the refuse or water portions, or the liquid portions may be pumped off into movable tanks, and afterwards discharged and disinfected whilst the solid matter is retained in the porous or perforated receptacle, which is so fitted as to be capable of easy removal and replacement by attendants provided for the purpose.—Patent Abandoned replacement by attendants provided for the purpose. Patent abandoned.

Patent abandoned.

3343 G. F. Morant, Fenchay. Packing game. Dated November 3, 1868.

The case for this purpose is made of openwork material, so that the air circulates freely through it. Also, in order that no packing material, such as the heather now commouly used, may be necessary, means are provided for securing each head of game in its place in the package. The case is made of strong wirework supported on a suitable frame, furnished with eyes, by which it is secured to the pack saddle; or the sides of the case, if preferred, may be made of perforated zinc, and galvanized or painted. The case is fitted with shelves, the bottoms of which also are of wirework, and which may have fixed to them a number of straps with buckles or elastic bands, by which each head of game may be separately secured on the shelf.—Patent completed.

3344 W. R. Lake, Chancery-lane, E.C. Alarm appa-

3344 W. R. LAKE, Chancery-lane, E.C. Alarm apparatus for boilers. (A communication.) Dated November 4,

This relates to an automatic apparatus for indicating a deficiency of water in steam boders. The apparatus is provided with a whistle or other similar instrument, which is attached to a tube. The lower end of the tube is open and a little below the desired water line; when the water sinks below this line steam enters the tube, and by its heat expands the same. The upper end of the tube is closed and provided with a socket, which carries the whistle. The socket communicates with the steam space of the boiler, and is provided with a valve. The tube carries a lever, which is arranged to open the valve and sound the whistle when the tube is clongated. The lever is held by a rod, which is attached to the lower end of the tube, and whose length is not affected by the admission of steam to the said tube.—Patent abandoned.

3345 B. W. BECKLEY, Ludgate-hill, E.C. Pen rest. This relates to an automatic apparatus for indicating a

2345 B. W. BECKLEY, Ludgate-hill, E.C. Pen rest.
Dated November 4, 1868.
This consists in the application of an ordinary horse shoe or other shaped magnet, suitably mounted, as a pen rest, whereby the pen is rendered more durable, and the inking of the fingers, consequent on resting the pen in the ink bottle, is avoided.—Patent completed.

ink bottle, is avoided.—Patent completed.

3346 M. SAMUELSON, Hull. Pressing fatty substances.
Dated November 4, 1868.

This consists in so adapting an ordinary pair of rollers for rolling iron or steel or other ductile metal, that the desired parallel or tapered form of the plate, together with the necessary recessed form thereof, with corrugations or ridges and furrows across the said recess may be produced at the same time by the simple operation of rolling, and thus adapting them for the above purpose.—Patent abandoned.

3347 E. HOLDEN, Baildon. Preparing wool. Dated No-

rember 4, 1868.

The object of this invention is to operate more effec-The object of this invention is to operate more enectively upon the fibre and at the same time to reduce the number of operations upon it by passing it through apparatus arranged to effect a draft on such fibre, between sets of gill combs, and it is found convenient to employ drawing rollers as the means of effecting such draft between the sets of gill teeth.—Patent completed.

3348 A. V. NEWTON, Chancery-lane, E.C. Atmospheric cater elevators. (A communication). Dated November 4,

1898.

This consists, first, in constructing water-elevating engines with a double cylinder—that is to say, an upper and a lower cylinder, the latter of which is, properly speaking, the condensing cylinder. The invention also includes certain devices for condensing the steam (which is let into the upper cylinder to dostroy the vacuum and allow the water to fall to the level of the discharge valve), by the momentum of the falling water, which enables it to pass through a floating piston of the upper cylinder into the water in the condensing cylinder.—Patent abandoned.

3349 E. T. HUGHES, Chancery-lane, E.C. 3349 E. T. HUGHES, Chancery-lane, E.C. Furred threads and fabrics. (A communication). Dated November 4, 1868. This consists, first, in an improved system and mechanical arrangement for coating threads or yarns of wool and other fibrous materials with the hair or fur of animals, and afterwards employing them to form fabrics having all the appearance of real skins of fur, with their lightness, warmth, and peculiar aspect, and also for forming fabrics having plain or even surfaces: and, secondly, in forming furred fabrics by causing fur to adhere to a woollen or other fabric used as a foundation.—Pattent abandoned, 3350 J. W. and J. Hottr and J. Mayne, Balton (1964).

other rather used as a nonnamon.—rather abandoned.

3350 J. W. and J. Holt and J. Maude, Bolton. Spinning and doubling. Dated November 4, 1868.

This consists in dispensing with the ordinary drumbands and warves, and driving the spindles of such machinery in a novel manner by friction wheels, the periphery of the driving wheels of such frictional gear being parallel with the axis of the horizontal driving shaft, and

a weighted boss being secured to the lower extremity of the spindles covered with leather or other suitable mate-rial, cupped to the proper shape, so as to present a narrow or feather edge to rest upon the periphery of the driving wheel.—Patent completed.

wheel.—Patent completed.

3332 M. SAUTLER, Paris. Preserving substances. (A communication). Dated November 4, 1868.

This consists in using for this purpose the vapours which are disengaged by the distillation of the tarr of coal, wood, resin, or of natural tar, or of the mineral oils, such as naphtha or petroleum. These matters are distilled at a temperature of 100 kg, to 150 kg. Centigrade, or similar vapours may be obtained by distilling at a suitable temperature matters derived from those above mentioned.

—Patent completed.

2353 S. Ward and W. Hurst and J. Turr, Farnworth,

Patent completed.

3:53 S. Ward and W. Hurst and J. Turr, Farnworth, Looms. Dated November 5, 18:63.

This consists, first, in dispensing with the shoulder and stop, and in checking the shuttle by means of a check strap, which is connected to the shuttle box frame and to the front of the boun side. At the end of the shuttle when the drop box rises or falls. Second, in a positive taking apmotion with one plain roller. As the cross beam increases in diameter, it raises a lever which is moved to and fro by an eccentric or other equivalent on the second motion shaft or other part of the born; the lever moves the catch of the taking up ratchet wheel, and the speel there of is reduced in proportion to the increasing diameter of the cloth on tae beam.—Patent completed.

3354 T. Burt, Wandsworth-road. Floiting dredgers. (A

3354 T. BURT, Wandsworth-road. Floating dredgers. (A

3354 T. BURT, Wandsworth-road. Floating dredgers. (A communication) Dated November 5, 1863. The inventor makes a centrifugal mud pump by fixing two or more vanes to a shaft, and supporting it by suitable bearings; these vanes he partially encloses in a cylindrical case, having an outlet formed on one side, and an inlet on the top and bottom, the one on the top being furnished with a valve, and that on the bottom with a suction pipe. This pump, which may be worked by steam or other power, he supports upon a floating versed, and mounts it in such a manner as to admit of its having a radial monthly manner of the power of the power of the power of the suit of the side opening of the case, the inventor fixes flexible-jointed pipes, connecting the pump with the shore or place for depositing the material lifted.—Patent abandoned.

3355 H. JEWITT, Kentish Town. Tov houses. (A com-

attent.—Patent abandoned.

3355 H. Jewitt, Kentish Town. Toy house. (A communication). Dated November 5, 1868.

This consists in forming slabs or blocks for the erection of toy houses with mortice joints at one or both ends, sides, or margins thereof, so that the joints may fit into each other, by which means various styles of architectural buildings or structure, such as castles, churches, arches, temples, and many others, may be constructed in a more substantial and secure manner than with the present form of plain blocks. These slabs are preferably oblong or square, but they may be made of any shape to suit the style of building or erection for which they are intended.—Patent comming or erection for which they are intended.—Patent coming or erection for which they are intended.-Patent com pleted.

3356 T. ROBINSON, Widnes. Iron and steel. Dated Novem-

ber 5, 1868.

The object is to improve the quality of iron and steel by The object is to improve the quality of iron and steel by removing sulphur and phosphorus therefrom, and to facilitate the production of iron and steel of any desired quality. For this purpose, the inventor introduces into cupola blast or other furnace of that class, in which the body of the fuel is direct contact with the ore to be smelted, or the pig or other iron to be remelted, whether such furnaces are worked with a plenum blast or induced current of air, nitrate of sola, nitrate of potash, or other salt or salts with like properties.—Patent abandoned.

3377 R. COOK Hathersone Bellin reset, Patel March

3357 R. Cook, Hathersage. Bobbin spools. Dated November 5, 1868.

ber 5, 1868. This consists in the making or manufacturing all such articles of sheet, brass, zinc or other metal, capable of being rolled into sheets and pressed or formed to the required shape and size, whether they are to be employed in flyer cap-cup or other kind of spinning and twisting machinery.

—Patent abandoned.

3358 R. NEEDHAM, Dukindeld. Scrapers. Dated November 5, 1868.

3393 M. NEDHAM, DIKINHIELD Scrapers. Dated November 5, 1868.

This consists in so arranging the scrapers of fuel economizers that, notwithstanding the constant wear to which they are subjected, their edges will constantly be kept in contact with the tubes or pipes, so as effectually to clear off all adhering soot. The scrapers are carried by frames or carriers, to which the necessary motion is imparted by any suitable arrangement of mechanism. These scrapers may be of certain already known forms, that is to say, they may be in the form of plates, out of one side of which a semicircular piece is cut corresponding to the diameter of the pipe, so that two of these placed face to face will just fit round one of the pipes. Or they may be in the form of long plates, out of one side of which a number of semicircular pieces are cut corresponding in size and position to the pipes, so that two of these blades placed face to face will just fit round one row of pipes.—Patent completed. completed.

completed.

3359 B. Hunt, Lincoln's Inn. Electro-physiological battery. (A cosmunication). Dated November 5, 1868.

This consists in forming a battery for action on the human frame by arranging pairs of plates of dissimilar metals upon any desirable flexible and non-conducting base, and insulating cach pair of plates from the next pair, and insulating all from the base by any good insulating material, like rubber cloth. These plates may be of any convenient shape or size.—Patent completed.

3360 J. CLARK, Kendal. Shaping wood. Dated Novem-

3360 J. Clark, Kendal. Shaping wood. Dated November 5, 1868.
A hollow spindle is mounted on a headstock with bearings, in which it is capable of sliding and rotating, or the headstock may slide instead of the spindle. This spindle carries at one end two or more cutters (and may also carry a boring bit). A sliding collar having inclined slot holes, is applied outside the hollow spindle, which acts upon one or more of the cutters, so as to move the cutting edges nearer to or further from the axial line of the said spindles. The spindles and collars or the headstock are caused to slide by means of cam grooves suitably formed and arranged to operate thereon at proper times. Nipping jaws are also employed, which are opened to receive the wood to be operated upon by levers actuated by a cam or eccentric, and closed by weight or spring to hold the wood, the jaws being suitably formed to bite and hold theroon.—Patent completed.

3361 A. REID, Arbroath, N.B. Rolling tobacco. Dated tovember 5, 1868.

3361 A. Rein, Arbroath, N.B. Rolling tobacco. Dated November 5, 1868.

This consists in two face plates opposite to each other, and between which the roll is formed. Below or at one side of the face plates a guide for laying on the twist travels backwards and forwards. This is actuated by a ravers backwards and forwards. This is actuated by a lever or rod connecting it to the reciprocating slide below, motion being duly communicated thereto. Above the face plates a retarder is placed for regulating the required drag upon the twist as it is rolled up between the face plates.—Patent completed.

3362 J. CORBETT, Clerkenwell. Railway carriages. Dated November 5, 1868.

November 5, 1868.

The continuous or consecutive buffers are arranged so as to have a traverse both ways, that is, in and out of the carriages, and to meet in the middle when the springs are set up, and thus form one rod right through the carriages, and if driven in with force sufficient to set up the springs, the buffer ends strike the buffers in the next carriage, and so on from carriage to carriage, and thus relieve any single carriage from the violence of the shock in the event of a collision. The buffer rods going right through the train from carriage to carriage, the foremost carriage or the engine (if it be at the front) is the first that is struck after the springs of the buffers are set up till the rods meet.—Patent completed.

3363 A. L. BRICKNELL Stratford-on-Avon. Rotary engine. Dated November 5, 1868.

This relates to a patent, dated June 7, 1867 (No. 1871). In constructing rotary engines, in place of making the cylindrical centre-piece of the engine in pieces, which are botted or otherwise joined together, as heretofore, the inventor casts it in one piece upon its shaft in the manner hereinafter more fully described, and he afterwards turns it truly and slots out the recesses for the pistons, or he forms the recesses by casting the metal around boxes of sheet steel or iron, or he introduces metal cores or chills into the casting to produce the recesses, and he draws them out as soon as the casting is set. In some cases he uses, in place of the metal cores, sand cores, moulded in an iron box, made for the purpose with great accuracy and truth. In order to give more strength to the cylindrical centre-piece, the inventor hoops it with wrought iron around the flanges, which he prepares to receive the hoops by turning them slightly hollow. For engines of small size, he uses for casting the centre-piece a white metal alloy in place of casting. The helloy fluid most advantageous consists of nine parts of zinc and one part of tin, or thereabouts.—Patent completed.

3364 J. EDWARDS, Hackney. Harnen. Dated November 5, 1868.

This consists in making roller bolts hollow with a slot

3364 J. EDWARDS, Hackney. Harness. Dated November 5, 1868.

This consists in making roller bolts hollow, with a slot or slots in one side, so that the traces can be dropped in from above. The traces are made thicker at the ends to prevent them being drawn through the slots, a cap is formed to go on the top of the roller bolts, and cover up the opening: also in making back bands jointed in the middle, so as to be able to make the tug and back band in one piece; also in making back bands jointed in the middle, so as to be able to make the tug and back band in one piece; also in making hames with a screw at one ond to connect a chain to the ends, instead of the present leather strap; also in the application of rollers or projections inside the tugs to prevent rubbing the saddles; also in making screw cock eyes for shortening traces; also in making strew cock eyes for shortening traces; also in making the bearers of double harness to terminate in a spring to prevent the traces lifting up the bearers when the horse is drawing.—Patent abandoned.

3365 W. R. Lakig, Chancery-lane. Pegging boots. (A communication). Dated November 5, 1863.

This consists in the details of construction and arrangement of mechanism for cutting the wire for intermittenity feeding it to the action of vertical line with the nail driver and nail tube for feeding the shoe after each nail is driven, in such manner as to ensure the insertion of each nail into the hole punctured for its reception by the awl, and for holding the edge of the shoe under the feed foot at all times or at all points along each edge at a uniform angle with relation to the surface of the feed foot and the vertical line of the driver.—Patent abandoned.

3366 A. H. Robinson, Dublin, Cocts. Dated November 6, 1868.

3366 A. H. ROBINSON, Dublin. Cocts. Dated Novemers, 1868.
The body of the improved to be a second to the control of the contro

ber 6, 1868.

The body of the improved tap is provided with three branches, one leading direct from the main and provided with a spherical or other valve composed of cork, vulcanized india-rubber, metal, or other suitable material for opening and closing the communication, another leading to the rising main for supplying the house elstern, and the third affording the requisite supply for ordinary domestic purposes, as may be required. The valve is opened by a rod or spindle which passes through an opening in the front of the tap, and is connected to an internal screwed cap which screws on to an external screwed boss forming part of the body of the said cap, being provided with the usual crutch for turning the same.—Patent abandoned.

usual crutch for turning the same.—Patent abandoned. 3367 C. ARCHER, Holloway-road. Cigars. Dated November 6, 1868.

The inventor forms upon the circumference of the cigars, by means of pressure, longitudinal grooves or channels, varying in number, shape, and size, according to requirements.—Patent abandoned.

continues, waying in unitaries, and size, according to requirements.—Patent abandoned.

3368 J. H. Johnson, Lincoln's Inn. Pigments. (A communication). Dated November 6, 1868.

This consists in the purilication or removal of solid foreign matters from the carbonate of lime, in order to use it for pigments. This is effected by sifting the carbonate, whilst in a perfectly anhydrous state, in apparatus specially adapted for the purpose. One form of apparatus which will be found to answer well in practice, consists of two concentric polygonal screens placed at a slight inclination, and attached to a central longitudinal shaft to which rotatory motion is imparted by a strap and pulley, or otherwise, the screens being enclosed in a tight casing of wood or metal. The inner screen which projects beyond the outer one at the delivery end, is composed of wire gauze, and the outer one of fine textile fabric, and along the arms which carry these screens are sliding weights, which, as the arms revolve, alternately fall from and towards the centre, thereby giving a succession of shocks or blows to the screens, which have the effect of shaking off any fine particles which may be adhering thereto.—Patent abandoned.

3370 J. Samuel, Great George-street. Railway steam

thereto.—Patent abandoned.

2 3370 J. Samuel, Great George-street. Railway steam carriags. Dated November 6, 1868.

The boiler or boilers is or are firmly secured to the top table or platform of a "bogie" or "bogies" carrying the engine or engines at or mear to the centre, between the wheels of such "bogies" in a somewhat similar manner

to that described in the specification of letters patent granted to R. F. Fairlie, dated November 14, 1867, No. 3221. The locomotive or locomotives is or are made to support the ends of one, two, or more girder or "carrier frames," consisting of main girders framed together of any desired length at or near the centres of the "bogies," either above or below the plattorm, by means of a cross girder firmly fixed to the head of a centre pin, which fits into a hole or socket made in or near the centre of the engine frame or "bogie," and round which pin the engine is free to swivel or partially revolve. The girders may be continued parallel with each other to their junction, with the crosspiece or transverse girder fixed to the pin kead, or they may be narrowed towards their ends, so as to converge towards one centre and be firmly fixed to the entire pin head, or be formed into a boss to bear on the swivelling centre of the engine frame with a suitable hole in it, and through which a centre pin passes, thus permiting the swivelling motion of the engine.—Patent completed.

3371. I TAYLOR JUN Wiene Relies. Dated Novemers. pleted. 8371 J. TAYLOB, JUN., Wigan. Botlers. Dated Novem-

pleted.

3371 J. TAYLOB, JUN., Wigan. Bollers. Dated November 6, 1868.

This consists in doing away with the rollers for carrying the travelling bars, and instead thereof making use of either the ends of the bolts or joint pins, and also of the nuts on the other ends thereof, or the under sides of the bars themselves, and longitudinal slides or grooves attached to the sides of the firebox, as the means of supporting the bars on their passage through the firebox thereby allowing sufficient space for the passage of air up to and between the said bars. In Cornish and other similar boilers, the inventor carries the bars (after they have passed through the firebox from the front to the back thereof) down through the bottom of the firebox into and through a space below the boilers in order to get the bars back to re-enter the firebox. The invention also relates to improvements in the construction of the furnace doors of steam boilers, and consists in making the furnace doors hollow so that they may contain water whereby the fire is prevented from producing injurious effects upon the said furnace doors. The invention further relates to improvements in the construction of the fire bridges of steam boilers, and consists in making each of the said fire bridges hollow, to be so connected to its boiler as that the water in the boiler may freely pass through the said fire bridge, whereby instead of the fire bridge becoming burnt and injured by the fire, it becomes itself a useful generator of steam.—Patent completed.

3372 J. Parkort and W. Jones, Salford. Beetling fabrics. Dated November 6, 1868.

and injured by the fire, it becomes itself a useful generator of steam.—Patent completed.

3372 J. Parrott and W. Jones, Salford. Beetling fabrics. Dated November 6, 1868.

This consists, first, in dispensing with the vertical timbers or tailers and substituting in lieu thereof a succession of metal or other hummers attached by an elastic web or other suitable connection to a shaft or roller revolving at such a velocity as to throw out by centrifugal force the hammers which are brought in contact with the cloth or other material to be operated upon, the said cloth or other material having been previously wound on rollers provided for that purpose, or laid upon a horizontal table or other stationary surface. In making a beetling machine that will act continuously on the fabric, which is brought from any convenient number of batch rollers, and passed over a roller placed under the usual fallers, ounder the hammers acting by centrifugal force as above described, when the folds of fabric have passed over this roller they are wound continuously on a batch roller, or they are taken over guide rollers and brought a second time under the fallers or hammers, or they are otherwise disposed of.—Patent completed.

3378 F. C. Philippeson, Berlin. Pumps and fire engines.

this roller they are wound continuously on a batch roller, or they are taken over guide rollers and brought a second time under the fallers or hammers, or they are otherwise disposed of -Patent completed.

3373 F. C. Philippeson, Berlin. Pumps and fre enginet. Dated November 6, 1868.

3378 F. C. Philippeson, Berlin. Pumps and fre enginet. Dated November 6, 1868.

3378 F. C. Philippeson, Berlin. Pumps and fre enginet. Dated November 6, 1868.

3374 F. E. Martingal, the two sets of valves may be placed side by side.—Patent abandoned.

3374 F. E. Martingal, the two sets of valves may be placed side by side.—Patent abandoned.

3374 F. E. Martingal, the two sets of valves may be placed side by side.—Patent abandoned.

3374 F. E. Martingal, the inventor bonds the ends of the roll or wire, of which the heap is made at right angles to the body of the haap, and thereby forms projecting ends or pins. To these ends of the hasp he joints or connects as plate in the following manner:—On the one end of the middle of the corn of the plate, and bending the said cars upon the plate into a tubular form, the heap is connected with the plate, the said hasp and plate being jointed to extend the plate, and bending the said cars upon the plate into a tubular form, the heap is connected with the plate, the said hasp and plate being jointed to the plate, and bending the said cars upon the plate into a duble check in a triple of the earth of the cars of the plate, and bending the said cars upon the plate into a duble check in a triple of the cars of the plate, and bending the said cars where the plate of the plate of

of the endless travelling firebar class, and instead of employing endless chains carrying transverse lirebars, as hitherto frequently used, he has a series of endless jointed firebars, constructed as hereinafter described, and placed side by side, so as to form an endless chain running longitudinally through the furnace, and passing round octagonal or other suitably formed rollers, one placed in front of the firedoor, and driven by a worm and wheel, or other suitable slow movement, and the other forming a carrier only, and being placed inside the flue in front of the bridge. The endless jointed firebars are placed over the two rollers, side by side, having air spaces between them, and are jointed together by transverse rods, into which stud wheels or stud so reteth fixed to the octagonal or other rollers gear, so as to ensure the steady and regular movement of the whole series.—Patent completed.

3377 M. A. F. MENNONS, Newgate-street. Forming screen breads. (A communication). Dated November 6, 1868. This consists in the application of a waging process, by neans of improved apparatus to the formation of screen breads on wrought-iron bolts.—Patent completed.

3378 W. JENNER, Clerkenwell. Corn flour jelly. Dated

3378 W. JENNER, Clerkenwell. Corn flour jety. Dated November 6, 1868.

The corn flour jety is made in the following proportions, viz.:—60z. isinglass, 20z. gelatine, jtb. glycerine, jtb. corn flour, i j galton diluted water.—Patent completed.

3379 W. BROUGHTON, Finsbury Market. Kitchen ranges Dated November 6, 1863.

The inventor forms each of the lugs or flanges with a slot, through which the stem of the screw may pass freely, and be then screwed into a nut, which is unable to turn by reason of one of its sides resting against the side of the plate or part upon which the lugs or flanges are cast.—Patent completed. Patent completed.

Patent completed.

3380 A. M. CLARK, Chancery-lane, E.C. Rojes, tack
dc. (A communication.) Dated November 6, 1-68.
In making a cable of any suitable dimensions, the inventor takes a number of yarns, strings, or twines, and stretchesthem equally, afterwards laying them together in bundles, without twisting. This may be done either by hand or machine. On this cylindrical bundle of yarns the inventor weaves a sheath or envelope, composed either of rope, yarn, string, or twine, or it may be of metal wire. In this manner he produces ropes, cables, and cordage of any required diameter, presenting externally the appearance of blind cord. The yarns, strings, or twines are previously passed through a solution of gutta-percha, in order to impart sufficient suppleness to enable the ropes so made to pass round pulleys of small diameter.—Patent completed.

3341 J. C. Haddan, Vincent-square, Westminster. Cannon

completed.

334 J.C. Haddan, Vincent-square, Westminster. Cannon reads and carriages. Dated November 7, 1868.

This consists in constructing such wads of a somewhat yielding material, which will upset or squeeze into the rifling, and so close the windage, and enclosing or embedding in or combining with the material, discs or pieces of metal, or of some hard material, which by the upsetting may be driven into the rifling of the cannon, and into recesses in the projectile, and so become keys compelling the projectile to acquire the twist as they with it and the remainder of the wad are driven forward in the bore of the gun.—Patent completed.

3382 S. ARNOTT, Holloway. Braces. Dated November 7, 1868

1868.
The inventor employs straps, bands, or webs, which are crossed or connected to each other at the back; the front ends are provided with button holes as usual, and are buttoned to the trowsers, at of near the side seam, but instead of the ends which are usually buttoned to the back

1433 C. Cross and A. Heywood, jun., Manchester, and G. D. and T. B. Wilson, Cressbrook, Derbyshire. Improvements in velocipedes.
1439 T. Dunn, Pendleton. Improvements in the construction of velocipedes.
1440 W. R. Lake, Southampton-buildings, Chancerylane. An improved detergent or saponaceous compound.
1441 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in galvanic batteries.
1442 B. Latham, Westminster Chambers, Westminster. Improvements in ventilators for sewers, also applicable for deedorzing norsious gases arising in the processes of

for deodorizing noxious gases arising in the processes of certain manufactures.

certain manufactures.

1443 B. J. B. Mills, Southampton-buildings, Middlesex. Improvements in casting metals under pressure, and in apparatus and appliances therefor.

1444 J. A. Marden, Boston, Massachusetts, U.S.A. Having reference to steam and other enginery.

1445 J. B. Payne, Chard, Somersetshire. Improvements in the fittings for roller blinds, parts of which improvements are also applicable for suspending picture frames, and for coupling, joining, or connecting together the ends of ropes, cords, or bands.

1446 L. Wray, Ramsgate, Kent. Improved apparatus for crushing, grinding, and pulverizing quartz and other

1446 L. Wray, Ramsgate, Kent. Improved apparatus for crushing, grinding, and pulverizing quartz and other hard substances.

1447 A. Vickers, Old Broad-street, City. Improvements in connecting and sustaining the rails of railways.

1448 A. Henry, Edinburgh. Improvements in breechloading firearms.

loading firearms.

Dated May 12, 1869.

1449 C. H. Merritt, Brunswick-square, Middlesex. Improvements in apparatus for basting.

1450 J. Robey, Victoria Sugar Refinery, Newcastle-auder-Lyme. Improvements in sugar refining.

1451 E. T. Hughes, Chancery-lane. Improvements in tea and coffee urns.

1452 P. W. Flower, Briton Ferry, Neath, Glamorganshire, and W. Flower, Great Winchester-street-buildings, City. Improvements in the method and process of producing impressions upon tin and terne plates and sheets of metal, and in furnaces or ovens for heating and drying of metal, and in furnaces or ovens for heating and plates or sheets which have received the required impres-

sions.

1453 H. Ing. St. John-street-road, E.C. Improvements in fastenings and clasps for albums, books, and other like

1454 J. B. Handyside, Glasgow. Improvements in

wheels.
1455 T. Bullivant, Ledbury-read, Bayswater, Middlesex.
Improvements in window sashes, shutters, and frames,
and in pulleys for the same and for other purposes.
1456 H. Robinson, Skipton, Yorkshire. Improvements
in the construction of kilns for burning limestone, chalk,

cement, or for calcining ores.

1457 J. L. Greatorex, East Grinstead, Sussex. Improve-

1457 J. L. Greatorex, East Grinstead, Sussex. Improvements in urinals.

1458 P. W. Flower, Melyn Tin Plate Works, Neath, Glamorganshire, H. Nash, India-buildings, Water-street, Liverpool, and R. Heathfield, Birmingham. Improvements in coating sheets of metal with other metals.

1459 J. H. Johnson, Lincoln's Inn-fields. Improvements in saw teeth, and in machinery or apparatus for forming the same.

1460 F. R. A. Glover, Brading Isle of Wight. Improve-

188W teeth, and in machinery or apparatus 18 same. 1460 F. R. A. Glover, Brading, Isle of Wight

1460 F. R. A. Glover, Brading, Isle of Wight. Improvements in anchors, and in the gear for facilitating the weighing and boarding of anchors.

1461 A. V. Newton, Chancery-lane. Improved machinery for expressing juices from organic matters.

1462 W. F. de la Rue, Bunhill-row, City. An improved method of obtaining a water mark on paper, and in apparatus authors of the sain.

ratus employed therein.

ratus employed therein.

Dated May 13, 1869.

1463 V. de Stains, Shepperton Villas, N. Improvements in wheels, treadles, and brakes, principally applicable to bicycles and other light carriages.

1464 E. V. Newton, Oxford-street, and P. M. Crane, Manchester. A new or improved composition for coating ships, boats, and other surfaces, and for protecting and preventing the fouling thereof.

1465 J. Timmins and J. Gayton, Birmingham. A new or improved lever fastening, for securely holding in a state of tension cords, cables, wire ropes, chains, or the like.

state of tension cords, cables, who reports in window like.

1466 H. Luke, Manchester. Improvements in window sashes, and in fastenings for the same.

1467 W. A. Lyttle, Grove, Hammersmith. Improvements in electro-telegraphic apparatus.

1468 T. G. F. Dolby, Forest Gate, Essex. An improved apparatus or valve suitable for the admission of air to feeding bottles and for other useful purposes.

1469 J. Townsend and P. Forbes, Glasgow. Improvements in refining or treating oils and fats, and in apparatus therefor.

1470 I. and G. Battinson and T. Whitehead, Halifax. Improvements in machinery for combing wool and other

fibres.

1471 J. Fawcett, Huddersfield. Improved means or apparatus for measuring oil or other liquids.

1472 C. Ferguson, Glasgow. Improvements in the washing, brushing, filling, and corking of bottles, and in the means, apparatus, or mechanism employed therefor, part of which mechanism is also applicable for other purcease.

poses.

1473 J. Bownes, Mansfield, Nottinghamshire. Improvements in machinery or apparatus for steaming and compressing tobacco.

1474 A. Friedmann, Hatton-garden, Middlesex. An improved ornament for personal wear.

1475 W. Cadogan, St. Anne-street, Birkenhead, Cheshire. Improvements in couplings for connecting together the ends of driving straps or bands.

1476 W. Stephenson, Sculcoats, Yorkshire. Improvements in apparatus for facilitating the consumption of smoke in furnaces.

Dated May 14, 1869.

1477 I. and J. H. Storey, Manchester, and H. Lea and T. Lane, Birmingham. Improvements in means for controlling the discharge of water from stand pipes, drinking

trolling the discharge of water from stand pipes, drinking fountsins, and ball taps or valves.

1478 J. and J. Kippax, Bolton-le-Moors. Improvements in the means of weaving counterpanes or quilts.

1479 C. W. Lancaster, New Bond-street, Middlesex. Improved apparatus for concentrating shot.

1480 J. T. Griffin, Fleet-street, City. Improvements in the manufacture of knives and forks, and in handles for he same.

the manufacture of knives and lower, he same.

1481 W. Finley, Stockport, Cheshire. Improvements in

working and applying the brakes of railway carriages, and in apparatus connected therewith.

1482 H. B. Barlow, Manchester. Improvements in cases for bottles and glass or other cups.

1483 G. F. Henry, I. A. F. Bang, F. R. C. Monestier, and J. P. A. Figuier, Paris. An improvement in liquids for the lubrication of sheep's or other wool or other animal textile fibrous materials.

1484 M. Wolfsky, Pilgrim-street, Ludgate-hill, City. An improved sliding fastening or lock for purses, pocket-books, boxes, satchels, bags, and other similar articles.

1485 F. Hedley, Richmond, Yorkshire. Improvements in horse shoes.

in horse

1486 J. H. Johnson, Lincoln's Inn-fields. Improvements in horse shoes.

1486 J. H. Johnson, Lincoln's Inn-fields. Improvements in the treatment of beetroot and other pulps, and in the machinery or apparatus employed therein.

1487 C. E. Spooner, Bron.y-Garth, Port Madoe, Carnarvonshire, and G. A. Huddarf, Brynkir, Carnarvonshire, and G. A. Huddarf, Brynkir, Carnarvonshire. Improvements in the construction of railways.

1488 G. T. Bousfield, Loughborough Park, Brixton, Surrey. Improvements in apparatus for lifting building blocks of stone, concrete, or other material, and for disengaging such blocks from the lifting apparatus.

1489 C. H. Gardner, West Harding-street, Fetter-lane, City, and J. Bickerton, Oldham. Improvements in lithographic and zincographic cylinder printing machines.

Dated May 15, 1869. 1490 I. M. Hilbank, Greenfield Hill, Connecticut, U.S.A. in improvement in cartridges for breech-loading fire-

1491 V. R. Batchelor, Marylebone, Middlesex. Improved arrangements for giving motion to wheels, specially applicable for the propulsion of hand power carriages.

1492 S. Corbett, Wellington, Salop. Improvements in

cable for the propulsion of hand power carriages. 1492 S. Corbett, Wellington, Salop. Improvements in velocipedes.

1493 L. A. V. Dubourg, Leicester-street, Leicester-square, Middlesex. Improvements in the manufacture of gas for lighting and heating purposes, and in the apparatus employed therein.

1494 F. E. Saxby, Great Howard-street, Liverpool, and L. M. McGeorge, Upper Pitt-street, Liverpool. The purpose of conveying persons or things upon the common highway (or any other way or road whatsoever), which shall be named and known as the Planetery velocipedo.

1495 W. Wilkinson, Seymour-street, Euston-square, Middlesex, and M. Boss, Cleveland-street, Fitzroy-square, Middlesex. Improvements in embossing, printing, enamelling, and ornamenting glass, fmetal, wood, canvas, or other woven prepared fabrics or other substances, and the preparation of the material or materials and ingredients employed therein, and machinery or apparatus appertaining to a part thereof.

1496 J. S. Jarvis, Wood-street, City. A seamless collar and tie combined.

and tie combined.

1497 T. Berney, Bracon Hall, Norfolk. Improvements in the mounting and working of defensive armour for the protection of ordnance in battery and in ships' fortifications and elsewhere, and in apparatus connected there-

with.

Dated May 17, 1869.

1498 F. Kohn, Robert-street, Adelphi, Westminster.
Improvements in the mode of extracting the juice from
sugar cane, beetroot, and other plants.

1499 R. Bodmer, Osborne House, Holland Park, Middlesex, J. J. Bodmer, Newport, Monmouthshire, and L. R.
Bodmer, Lansdowne-road, Notting Hill, Middlesex. Improvements in firegrates, applicable to steam boiler furnaces and other furnaces.

1500 R. Wilson, Patricroft, near Manchester. Improvements in machinery for preparing to be spun, and for

ments in machinery for preparing to be spun, and for spinning and doubling, cotton and other fibrous materials. 1501 H. de Garrs, Summerfield-street, Ecclesall-road, spinning and doubling, containing the spinning and doubling, containing the spinning and coupling the spinning that the

low, Sheffield. Improvements in the manufacture of spring knife cutlery.

1503 R. Harlow, Heaton Norris, Lancashire. Improvements in hot water boilers used for heating purposes.

1504 D. Hitchen, Halifax. Improvements in looms for

weaving. 1505 A. Dunn and A. Liddell, White-street, Southwark. 1505 A. Dunn and A. Liddell, White-street, Southwark. Improvements in the construction of metal cans or tins. 1506 C. E. Brooman, Fleet-street, City, patent agent. Improvements in apparatus for applying brakes on railways. (A communication).

1507 T. Wright and I. Fox, Nottinghamshire. Improvements in the manufacture of lace made on bobbin-not or twist-lace machines, and in the machinery or apparatus employed therein.

1508 S. W. Clark, Tower Royal, City, and W. R. Sykes, Clapham, Surrey. Improvements in hand signal and other railway lamps.

1509 W. E. Newton, Chancery-lane. Improvements in factory sliver cans.

ctory sliver cans.
1510 W. R. Lake, Southampton-buildings, Chancery-

lane. 1511

1510 W. K. Lake, Soutasmpton-outlangs, Chancery-lane. Improvements in revolving firearms.

1511 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in apparatus for drying sugar.

1512 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for forming the threads of metal screws.

NOTICE.—Having received communications from persons NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

Science and Art .- A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the the great power of skilled mechanical fabour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated given [41]. Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brooches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to and they cannot be too strongly recommended to those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[ADVI.]

# MECHANICS' MAGAZINE.

LONDON: FRIDAY, MAY 28, 1869.

CONVERSAZIONE AT THE INSTI-TUTION OF CIVIL ENGINEERS.

THE president of the Institution of Civil Engineers, Mr. Charles Hutton Gregory, held a conversazione at the house of the Institution in Great George-street, Westminster, on Tuesday evening last. It was exceedingly well attended by members of the engineering profession and leading men of science, about a thousand gentlemen, we believe, having honoured the president's invitation. Before passing to the interesting objects with which the hall was well stocked, we must first glance at the building itself, which has been greatly altered and improved since this time last year. The exterior of the house remains the same. but the acquirement of adjacent property has enabled a vast change for the better to be made in the interior. On the left of the entrance hall is the secretary's room, 24ft. long by 17ft. wide. Beyond this is the cieras of a room 17ft. long by 16ft. wide. On the operation occasion, these two rooms were thrown into one, and formed a spacious cloak room. Leaving the inner hall, which is well tesselated with coloured marble, we pass the foot of the main staircase, and, after going down five steps, we arrive in the lobby, leading, on the left, to the council room, towards the right to the members' reading and writing room, and further, on the extreme right, to the lavatories and water-closets. ing and writing room occupies an area of 40ft. by 28ft. 41in., and is supported upon four columns, two of which stand almost in the centre of the apartment, and the other close to a movable partition, which shuts off the council room from it. On Tuesday evening, these rooms were thrown into one, and made a splendid refreshment and crush room. Returning to the main staircase, we ascend it. and find ourselves in the library, which is now a handsome room 42ft. by 28ft. first and second floors of the old building have been thrown into one, and a gallery, supported on brackets, is carried around the room at the old upper floor level. This gallery is wide enough to contain bookcases and leave space enough for stools and desks for readers. The library is illuminated with two 28-burner sunlights, and sufficient ventilation is secured by gratings in the ceiling.
On the same level as the library is the

lecture hall, which has a clear area of 60ft. by 40ft., with a height of 30ft. from the floor to the springing of the dome, by which the room is lighted. There are four entrances to the theatre, the doorways of which are hand-somely executed in oak. The principal entrance opens from the landing at the head of the main stairs, a landing 6ft. wide, and extending from the meeting room to the library. A second access is obtained by a door on the extreme left, by a gallery parallel to the landing, which is approached from the library, and is intended on ordinary occasions for the entry of members who arrive after the proceedings of the evening have commenced. To the right, a staged gallery has been thrown over the back yard of the adjoining premises to the end of the meeting room, and two more doors open from this gallery The sides of the theatre are treated with Doric and Ionic pilasters, terminating in enriched cantilevers and cornices at the ceil-ing. The bays left between the pilasters are filled with pictures belonging to the Institu-tion. One of the most admirable features in the arrangement is in the provision made for the convenience of the host of visitors on

circulation is insured on the ground floor, in the refreshment room, and upstairs. The side entrance to the theatre from the library, as well as the main entrance at the head of the flight of stairs, afforded ample accommoda-tion for the streams of guests which were moving from one part of the building to another on Tuesday evening.

The lighting and ventilation of the theatre have been effected on the best principles. In the day time, the light is obtained from a central dome, 19ft. in diameter, and from eight lunettes. By night, the theatre is illuminated by three sunlights; the main or central one in the middle of the dome has 63 lights, and the two side ones 28 lights Two grated openings are provided in the ceiling for ventilation, and thirteen more of these openings, placed around the room about 15in. above the floor, admit the warmed air, forced from the basement, at the rate of 400,000 cubic feet per hour, being an allowance of 800 cubic feet per hour for 500 people. The supply of fresh air is taken from the outside of the building, and is carried along an underground channel, leading into the basement. At the extremity of this channel is fixed a fan, driven by a onehorse gas engine, by which the air is forced into an air chamber, where it is warmed in winter and cooled in summer. Thence it passes into a series of air channels, which convey it to the vertical air flues, constructed in the walls of the building, and by means of which it is uniformly distributed. The warmed air enters the theatre through the gratings, and beneath openings left for the purpose in the risers of the platform, beneath the rows of seats. For warming the air, there is a series of hot water pipes, 4in. in diameter, disposed in horizontal tiers, and so arranged that the entire volume of air used for ventilation must be passed amongst the spaces between them before it leaves the chamber. The axis of the fan used for forcchamber. ing the air into the building has its axis parallel with that of the air channels, and it carries two blades placed at 50deg., the diameter being 3ft. Means have also been provided for filtering the air before admitting it, and in summer a cold water spray is forced against a fine wire gauze screen covering the mouth of the channel, to cool the air on its The admission is regulated by passage. valves, which are placed in the different branches. The whole arrangements are exceedingly satisfactory, and if any be disposed to cavil at one or two peculiarities in architectural detail, which are to be found in the front portion, they must remember that the architect was cramped in his operations by the fixed and irregular boundaries of the abutting property. Mr. J. H. Wyatt is the architect, and he has been assisted by various members of the Institution. Mr. C. H. Gregory, the president, and Mr. James Forrest, the secretary, have been unceasing in their exertions during the time the improvements have been going on, and to them the members owe a debt of gratitude for their services in the matter.

Having given our readers some idea of the new arrangements at the house of the Institution, we will turn to the objects of interest which were exhibited last Tuesday On entering the hall, our attention was first arrested by a collection of small arms representative of those used, and to be used, in the British service. These were lent by General Lefroy; and conspicuous amongst them was the Martini-Henry rifle, which attracted considerable attention, every one who handled it quickly becoming familiar with its manipulation. There were also specimens of other arms with which our readers are already familiar. There was a clever portable cleaning apparatus for military breech-loaders, which was designed by Mr. C. E. H. Healey to obviate the wearing

one of which is fixed by a small strap on the stock of the rifle, just behind the lock, the other being mounted on a cap which fits over the muzzle of the piece. The brass jag, around which the tow is wrapped, is attached to two pieces of cord, one at each end. In use, one end of the cord is dropped through the barrel, brought out at the breech, passed under the pulley, and hooked to a wooden handle on the other end of the cord, which is brought over the pulley at the muzzle. handle being worked up and down, the tow inside effects the cleaning of the barrel with less labour and more rapidly than the steel rod, whilst the rifling is preserved from damage by the rod. Mr. E. H. Newby sent a Henry breech-loader out of which more than 30,000 rounds had been fired; the rifling showed no signs of deterioration whatever. Mr. Newby also exhibited sections of the Henry cartridge, showing its construction, and specimens of the Henry rifling. He also sent a pouch for breech-loading cartridges, which was designed by Major General Morris, of the U.S. army, and which was used in the Indian campaign. It has a swivelled and a fixedrack, which are conveniently arranged for use in quick loading. A simple apparatus for disengaging ships' boats was also exhibited by the same gentleman. This arrangement is applied to the splendid new passenger steamers of the North Ger-Lloyds, and is now being adopted by other steamship companies. Close by, was a model of Messrs. Green's well-known patent fuel economizer, with its scrapers and gearing, all which have recently been described in our pages. Messrs. Howard, of Bedford, sent a model of their safety boiler, which is built up of wrought-iron tubes, and which continues to increase in favour with steam users. Close handy, was an illustration of the newly revived system of locomotion by the velocipede, one of which, a bicycle, was sent by Messrs. Meredith, of Bankside.

Rock boring and coal cutting machinery was well represented by examples of these by Mr. Brunton, Messrs. Carrett and Marshall, Mr. Doering, Mr. Firth, &c. Mr. Doering had a model showing his most recent improvements in boring machinery, which will be found fully described and illustrated on another page of our present issue. The Maury Barometer Company sent specimens of this useful instrument, which is about the size of a chronometer, and may be similarly carried in the pocket. The Maury barometer contains a vacuum-box resembling that of the aneroid in appearance, but made of a material and by a process which give greater permanence to its elasticity in long ranges. The rise and fall of the box is measured by a fine micrometer screw, worked by the observer, and furnished with an index hand. The range may be extended through 24 barometric inches, if required, and the indications will still remain more accurate than those of an average aneroid through one quarter of the range. The main spring, which keeps the vacuum-box distended, is about four times longer than that of the best aneroids, and thus the spring is enabled to expand and contract through four times the range without more strain on each portion of its length. Messrs. W. A. Martin and Co. exhibited their balanced furnace doors, which possess a great command over furnaces for consuming smoke. The air is admitted only at the lowest point, and is brought to a focus in the mouth of the furnace, thus removing the "stive" or stagnant heat which is so destructive to boilers and furnaces. By the heat passing regularly round the flues or tubes, the boiler will expand equally and be preserved. These doors are mounted or axles, and swing inside the furnace to any angle required, accommodating themselves to the fuel, thus consuming smoke and intensifying the heat. They open outwards with the the convenience of the host of visitors on effect of the steel cleaning rods at present in slightest touch, and for charging or regulatconversazione nights. A thorough means of use. It consists of a couple of small pulleys, ing the fire are very simple in their action.

Digitized by GOOGLE

Close by these furnace doors was one of Blake's stone breaking machines, with which Mr. Marsden, the exhibitor and manufacturer, was industriously reducing to fragments a stock of flint stones. In this machine there is an eccentric, every revolution of which caused the lower end of the movable jaw to advance towards the fixed jaw about a quarter of an inch, and return. A stone dropped in between the convergent faces of the jaws is thus broken by the next succeeding bite; the fragments then fall lower down, and are broken again, and so on, until they are small enough to pass out at the bottom. readiness with which the hardest stones yielded at once to the influence of this gentle and quiet movement, and melted down into small fragments, surprised every one who witnessed the operation of the machine.

In sewerage matters, we have, first, a model of a machine invented by Mr. Baldwin Latham, for extracting the solid matter from The model exhibited was an exact sewage. representation of one of these machines now being made for Croydon. It consists of a large wheel, carrying grids of different sizes, and turned round by a turbine, which is worked by the natural fall of the water. gratings are arranged in two planes, filling up, as it were, the spaces between the arms of the wheel; and there are brushes, which clear away such solid matter as may adhere to them. In addition to these two ranges of gratings, there are others, set radially in a plane parallel to the axis of the wheel, and these are in appearance exactly similar to the step of a common step ladder. At the outer extremities of these radial gratings there are cups which lift up a quantity of water, and upset when the steps are in such a position that the water runs down instead of passing through the gratings. This sudden rush of water washes off the solid matter into a central trough, from whence it is conveyed away by an ordinary elevator. The turbine, which was designed and manufactured by Mr. Arthur Rigg, jun., has also several novel features, being so arranged that it can be taken to pieces for cleaning with the greatest The wheel and buckets lift up facility. without undoing any fastening, and the guides are held in their places by a simple locking contrivance, the reactive pressure of the water preventing them coming undone. These guides are separated into four equal groups, two of which are supplied by one large sluice, and each of the other groups has its own sluice, so that the quantity of water can be regulated according to the supply and the work to be done. Mr. Arthur Jacob exhibited a model of his patent ventilating apparatus, which consists of a cover somewhat similar to that in general use, and in the centre of which there is a circular opening to receive a cylinder of sheet iron. This cylinder is provided with a collar that prevents it from passing quite through the cover, and so suspends it in the top of the manhole or ventilating shaft. The cylinder, which is stopped at the lower end by a grating, contains a quantity of charcoal. broken into pieces of the size of a walnut, and is open at the upper end. Over the top of the cylinder there is a movable cover of cast iron, which serves to protect the char-coal from wet and grit, and which admits of the air from the sewer escaping, after having passed through the cylinder of charcoal. This apparatus will be found fully described and illustrated in our issue for April 2 last

Mr. T. J. Ellis sent some illustrations of the ABC sewage process. These consisted of specimens of the supernatant water obtained from the experimental works at Tottenham, Leicester, and Leamington, and the permanent works just completed at the last-named place, for carrying out the A B C process, together with

The process, as now carried out at Leamington, is the invention of Messrs. Sillar and Wigner, of Cornhill. It is very simple, and, to all appearance, perfectly effective. The to all appearance, perfectly effective. The A B C mixture, which is composed of animal charcoal, blood, and clay, with some alum and water, is stirred into the sewage, and the whole allowed to run into settling tanks. Here, nearly all the organic matter, together with the ammonia and phosphates, are precipitated in the form of large flakes, leaving the water clear, and nearly inodorous. The last traces of smell are removed by a small quantity of a solution of perchloride of iron. thus runs off clear, tasteless, and inodorous, containing about seven grains of organic impurity to the gallon, and a few mineral salts of a perfectly harmless nature. During the process of drying the precipitate, a little acid is added, to render it fit for agricultural The product is, at present, being manure. sold for £3 10s. a ton, and the demand for it at Leamington is stated to be greater than the supply. Specimens of this manure were shown. It is a nearly black powder, with a smell resembling the finest hothouse leafmould. Mr. George Jennings, the sanitary engineer, exhibited illustrations of his appliances for the reception, treatment, and distribution of sewage or other waters. The tribution of sewage or other waters. sewage flowing from the sewer is received on a grating of proportionate size, through which the liquid sewage passes, first to a water-wheel, to which it gives motion, and then to the earthenware carriers direct for distribution, thus rendering all subsiding tanks unnecessary. The revolving of the water-wheel gives motion to an endless chain, which carries two sets of teeth, which are thus made continually to pass between the bars of the grating on which the sewage flows. These teeth, in their progress, comb from the surface of the grating all matters unfit for irrigation, and carry them forward, and down the shoot, to any receptacle prepared for them.

Steam pumps were represented, in the first place, by Messrs. Hayward, Tyler, and Co., who had a working model of their new pump, which successfully demonstrated its principle. As a full description of this pump appears on another page of this number of our journal, we need not here refer to it. Mr. W. Tijon exhibited his patent steam feed pump, of which we hope to have more to say shortly. Mr. De Rusett's patent steam pump is a very simple affair, no working parts being exposed. It makes its suction and forcing exposed. It makes its suction and forcing strokes at equal speeds; therefore, there can be no racing. The pump fills at any speed, from 1 to 150 strokes per minute, and that without knocking. This pump takes steam on the forcing stroke only, working against a regulated pressure, which is sufficient for the return or suction stroke. The depth of suction at which it is intended to draw is regulated by admitting more or less steam at regulated by admitting more or less steam at the suction side of the piston, so that, for high pressures and small suctions, its advantages are evident. Messrs. J. and H. Gwynne sent two models of the pumps for which they are celebrated. Messrs. Kittoe and Brother-hood exhibited a specimen of their Paragon pump, which, we understand, is coming into extensive use. Mr. J. C. R. Okes also sent two models of universal steam pumps. Finally, Messrs. Weston had a model of their Niagara pump and of their special steam pump.

Messrs. L. Sterne and Co. exhibited the result of a very interesting experiment in taking up the recoil of a gun. This was a pneumatic rubber buffer and a block of wood which had been used in one of Messrs. Vavasseur and Co.'s new gun carriages lately experimented upon at Portsmouth. The block of wood was inserted in the cylinder, along with the buffer spring, to take up the recoil of the gun. The wood was used as a sub-

At the first discharge, the gun went cldan home to the buffer, and the 5in. block of wood was compressed to  $2\frac{1}{4}$ in., but has since returned to  $3\frac{1}{4}$ in., whilst the spring has remained intact. The trial was made with a 6-ton gun, 22lb. charge of powder, and a 115lb. shot. The gun recoiled 4ft. 9in., and the rebound was 1ft. 9in. There was also a sample of rubber united to metal which had been torn apart, and which showed a beautiful fern-like fracture in the rubber caused by gradually increased pulling stress of 2,782lb. At this point, the rubber tore, but the junction of the rubber to the metal remained quite perfect and sound. Messrs. Sterne also sent several samples of their patent metallic rubber driving belts. They are composed of bands of steel covered and united with rubber. The steel gives the strength, and the rubber the adhesion. great advantage is that this belt is not affected by the changes of atmosphere, and therefore does not stretch and contract. One has been in use now for several months, and has never been altered or taken off the pulley since first put up, and more work is said to be got out of it than any other yet used in its place; neither is there any appearance of wear. It has also great superiority on the score of economy, for, when one side is worn out, the other can be used with equal results, and then, when both are worn out, the steel can again be united to new rubber.

Many objects of interest still remain to be described, but want of space obliges us, for the present, to bring our notice to a close, only to resume it in our next. We cannot, however, conclude without bearing testimony to the admirable arrangements which the executive of the Institution have devised for the convenience and comfort of the visitors. There was a splendid collection of paintings and other works of art, which, with the floral decorations, proved very attractive to those present.

#### A SPANISH INTERNATIONAL EXHI-BITION.

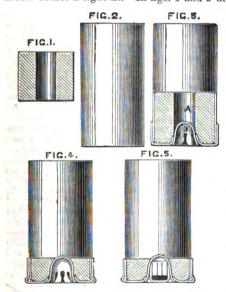

ONE of the best evidences that the internecine struggles which have of late troubled Spain are at an end, and one of the best guarantees that peace and prosperity are wished for and sought by the people, is fact that a proposition has been started for holding a Great National Exhibition at the Escurial. This speculation has received the encouragement of many influential persons in Madrid, who rightly judge that commercial and industrial prosperity ought to keep pace with political advancement. The Escurial with political advancement. has been selected for the exhibition, because it is convenient for such a purpose, and because Madrid does not offer the necessary facilities. Further, the Escurial—which is about 30 miles north-west of the city of Madrid, lying on the Northern Railway about an hour's journey down-is a far more pleasant place in the hot months than is the capital. Then, the building is already there, and most efficient for the purpose it would seem to be, for it is said to contain 16 courts, 1,111 windows outside, and 1,562 inside: 1,200 doors, 15 cloisters, 86 staircases, 3,000ft. of fresco painting, 89 fountains, and about 32 leagues of surface to walk upon. vast granite edifice, which was erected by Philip II., is built in the form of a gridiron, and forms a huge rectangular parallelogram, 744ft. from north to south, and 580ft. from east to west, and is divided up into long courts, which indicate the interstices of the bars. Towers at each angle of this parallelogram represent the feet of the gridiron, which is supposed to be lying upside down. From the centre of one of the sides a range of buildings abuts, representing the handle. This form was adopted in allusion to the instrument of St. Lorenzo's martyrdom-the building being dedicated to that saint. It some London sewage, showing the prestitute to fill up the case, as only one pneuwas intended to serve as a mausoleum and a cipitate at the bottom, and clear water above. matic spring was ready in time for the trials. was intended to serve as a mausoleum and a

was devoted, the handle being appropriated as a Royal residence. The chapel has three naves, 320ft. long and 320ft. high, to the top of the cupola. The pantheon, or royal tomb, is a magnificently decorated octagon chamber, 36ft. in diameter and 38ft. high. magnificent pile of granite, which has been called the eighth wonder of the world, is but a mere shadow of the past; its grandeur has departed, and now that such changes are being effected in the ecclesiastical administration of Spain, it has become a source of anxiety. Some of the leading scholars of the country have proposed to make the Escurial the general depository of all the archives now lying at Simancas, and in other places throughout the kingdom. The realization of such a project requires time and money, and, in the meanwhile, the silent hand of decay is at work on the uninhabited edifice, slowly rotting and undermining what it can never destroy. So nothing better, perhaps, at the present juncture, could have been devised than to utilize this building—itself one of the world's great shows—as an international exhibition. It will gather men of all nations together in the capital of Spain, which must be greatly to her gain in a commercial and an industrial sense. We look forward with interest to the further development of this scheme, to which we wish success. In no country has an exhibition of this character been held without the seeds of progress having been sown.

# MANUFACTURE OF CAPS AND CARTRIDGES. No. VII.

THE close of our last article brought us to the stage where the compound tubes of thin brass and paper, forming the case of the cartridge, were undergoing the operation of drying. They are subsequently cut to the proper size by a circular three-bladed revolving knife, care being taken that they are presented to it in the same direction so that the brass is wound inside the case. Sometimes, through carelessness or inadvertence, they are presented in the contrary direction, and, as a consequence, the metal is unrolled, and the paper torn to shreds. The next step is to unite the metallic end, which is furnished with its chamber and middle piece with the case. This operation is similar to that effected with cartridges for sporting purposes, except that no glue is used, as the expansion of the metal causes a tight fit. In figs. 1 and 2 are

represented a section of the middle piece, and an elevation of the cartridge case. In order to attach the case to the metallic end or bottom of the cartridge, it is placed upon a mandril, and one extremity of it brought into contact with a small die, which slightly turns up the edge of the case, and permits it to fit into the end. The case is again placed upon

the mandril, which being armed with a point, enters the hole left in the middle piece, and forces the chamber into it. This causes it to swell, and drives that portion of the case, between it and the metallic end, into such close contact that they are attached to one another in a manner which could not be surpassed by the use of the strongest glue. This completes the formation of the cartridge case, and it is then forwarded to the branch establishment of Moulineaux to be filled. fig. 3 is shown the case completely furnished with its middle piece A, chamber B, and small anvil for the purpose of percussion.

It is in this latter establishment that the

cartridges receive, so to speak, their finishing touches, and are ultimately rendered fit for the market. In addition to a large number of employés of both sexes, there are several very ingenious machines constructed for facilitating this portion of the manufacture. The principle of division of labour has been carried out in practice to the fullest extent. Each man, woman, and child, performs their allotted parts, which are adapted to their relative strength and intelligence. A number of boys seize upon the cartridges immediately on their arrival at Moulineaux, and commence to arrange them in large zinc boxes, holding about 200 each, in such a manner that all the openings are upwards. It is interesting to watch the different methods adopted by the boys to get their boxes filled in the quickest time. Some arrange them one by one in a most precise methodical manner, and, apparently, rather slowly; others fill both hands at once with the cases, and throw them into the boxes pell mell, afterwards shifting them so that the metallic end, which is heavier, should sink downwards. This, however, cannot be accomplished at once, but many successive shiftings and movings are neces sary before they are all settled in their places, so that there is not so much time gained as one might imagine, from the rapidity with which the several movements are effected. The boxes are then carried to the men who manipulate the machines. These latter never leave their respective machines, and their only duty is to attend to them, and supply them with the work they have to perform. The machines themselves were invented by the managing engineer, M. Calamel, and are termed "striking machines." They are They are mounted upon a cast-iron frame, and carry a couple of eccentrics, which act at the same time, but in opposite directions, upon the cartridge case, which is placed in a cylinder or matrix of suitable dimensions. The workwoman shifts the cartridges into a slide, at the end of which they are pushed on to a vertical table or large slab furnished with six matrices, which are rotated in such a manner as to bring them successively in the direction of the axis of the eccentrics. One of the eccentrics is furnished with a punch, in the inside of which there is a little hollow, in order that the shape of the chamber of the cartridge should not be altered by the pressure to which it is subjected. At the moment of stamping, a small distinguishing mark is imprinted upon the case of the cartridge, as a check upon the work performed by the machine. The other eccentric carries a disc machine. or plate having a small projection, corresponding to the ultimate form of the chamber. At every movement of the eccentrics, the punch and the plate approach each other, and compress the cartridge case in the interior of the cylindrical matrix placed in the line of their axis. This pressure, which is equal to many tons, causes the metallic end to swell out at the base, so as to fill up the spaces left in the matrix. A rim is formed at the base of the metallic portion, and this constitutes the work effected by the first "striking machine." In fig. 4 is represented a section of the cartridge at this stage, previous to its being submitted to the action of the

into a box, where they are again sorted and arranged by boys, who reject all which have received any deformation or damage by the operations they have undergone. struction of the second machine is very similar to that of the first, with the exception of a difference in the shape of the cylindrical matrix, which enables it to reduce the rim to a proper size and thickness. It also serves the purpose of fixing the brass lining to the metallic end, and thus prevents the escape of any gas through the weak parts of the base of the cartridge. In this condition, the cartridge is transferred to another part of the same workshop, to undergo the operation of priming. The priming charge, together with the anvil, is placed in a small hollow made in the centre of a movable disc. Upon this disc is also placed the cartridge, with its chamber exactly over the hollow containing the anvil and priming charge. By means of a lever, a small punch of the same diameter as the interior of the cartridge is caused to descend, and compresses the charge until a certain point is reached, upon which the cap rests. The diameters of the chamber and of the caps are accurately adjusted, so that the priming is strongly compressed in this opera-tion, and permanently fixed in its place. A section of the cartridge in this state is shown in fig. 5. It is now ready for the operation of gauging, which is effected by the aid of a slot or slide and two circular apertures. The slot is so constructed that any cartridge the thickness of whose rim exceeds the prescribed thickness, will not pass, and the two holes have unequal diameters. The one, the first to which the cartridge is presented, answers to the minimum, and the other to the maximum size allowed; should the cartridge fail to pass the second of these holes, it is rejected as too the second of these holes, it is rejected as too large, and if it passes through the first it is also rejected as too small. Those that are of the proper size, first pass the slot, then refuse to pass through the first hole, but traverse the second with facility. The diameter of the cartridges having been satisfactorily tested, the height is also ascertained with equal precision, and afterwards they are subjected to a close scrutiny upon other points. Any that have the priming compressed too much, or the wings of the chamber broken, or the anvil damaged, are summarily rejected. The cartridge cases may now be regarded as complete, and are despatched to that part of the premises where the operation of filling them is conducted. We must reserve an account of this for our next article.

# THE ROYAL INSTITUTION.

ON Thursday, May 13, also on Thursday, May 20, Dr. John Tyndall, F.R.S., continued his lectures upon "Light." In speaking of the "interference" of light, he said that it is necessary to clearly distinguish in the mind the difference between the motion of the wave itself and of the individual particles of ether composing the wave. The wave moves onwards, but the particles perform a very short excursion to and fro, much as a sea-fowl rises and falls on the billows of the ocean. When two series of waves of light from different sources come into contact with each other, a certain amount of disturbance or interference is the result. Supposing, that when waves of water come into contact, the crests of the one series of waves tend to occupy the same position as the crests of the other series of waves, union takes place, and another higher and more powerful series of waves is formed. If, on the other hand, when they first meet the crests of the one set of waves tend to occupy the depressions of other series of waves, the forces counteract each other, and stillness is the result. On the same principle, waves of sound may be obtained from two tuning forks, which here and there destroy achine. each other, and produce intervals of silence, known to musicians as "beats." Professor From the first machine, the cartridges pass Tyndall proved this by experiment. On the

same principle, it is possible, by adding light to light, to produce darkness.

The foregoing phenomena are intimately connected with those of the diffraction or the inflection of light. When a fine line of red light from a slit backed by red glass in front of the electric lamp is viewed from a distance through an opaque screen with a slit of variable aperture, an extraordinary appearance is observed. The slit in front of the lamp is seen as a vivid rectangle of light, but right and left of it is a long series of rectangles, decreasing in vividness, and separated from each other by intervals of absolute darkness. The lecturer explained that these intervals of darkness are caused by the interference of waves which destroy each other. He next explained how waves of light are measured, and closed by narrating the philosophy of the colours of thin plates. He said that when a beam of monochromatic light—say, of pure red, which is most easily obtained by absorption—fells upon a thin transparent film. tion—falls upon a thin, transparent film, a portion of the light is reflected at the first surface of the film; a portion enters the film, and is in part reflected at the second surface. This second portion having crossed the film to and fro is retarded with reference to the light first reflected. If the thickness of the film be such as to retard the beam reflected from the second surface, a whole wave-length, or any number of whole wave-lengths—or, in other words, any even number of half wave-lengths—the two reflected beams, travelling through the same ether, will be in complete accordance; they will, therefore, support each other, and make the film appear brighter than either of them would do taken singly. But if the thickness of the film be such as to retard the beam reflected from the second surface half a wave-length, or any odd number of half wave-lengths, the two reflected beams will be in complete discordance, and a destruction of light will follow. By the addition of light which has undergone more than one reflection at the second surface to the light which has undergone only one reflection, the beam reflected from the first surface may be totally destroyed. Where this total destruction of light occurs, the film appears black. If the film be of variable thickness, its various parts will appear bright or dark, according as the thickness favours the accordance or discordance of the reflected rays. Because of the different lengths of the waves of light, the different colours of the spectrum require different thicknesses to produce accordance and discordance; the longer the waves the greater must be the thickness of the film. Hence those thicknesses which effect the extinction of one colour will not effect the extinction of another. When, therefore, a film of variable thickness is illuminated by white light, it displays a variety of colours. These colours are called the colours of thin plates.

The colours of the soap bubble, of oil or tar upon water, of tempered steel, the brilliant colours of lead skimmings, Nobili's metallo-chrome, the flashing colours of certain insects' wings, are all colours of thin plates. The colours are produced by transparent films of all kinds. In the bodies of crystals we often see iridescent colours due to vacuous films produced by internal fracture. In cutting the dark ice under the ture. In cutting the dark ice under the moraines of glaciers internal fracture often occurs, and the colours of thin plates flash forth from the body of the ice with extraordinary brilliancy. Newton placed a lens of small curvature in optical contact with a plain surface of glass. Between the lens and the surface he had a film of air, which gradually augmented in thickness from the point of contact outwards. He thus obtained point of contact outwards. He thus obtained in monochromatic light a series of bright and dark rings, corresponding to the different thicknesses of the film of air, which produced alternate accordance and discordance. The rings produced by violet he found to be smaller than those produced by red, while

the rings produced by the other colours fell between these extremes. Hence, when white light is employed, "Newton's Rings" appear as a succession of circular bands of colour. A far greater number of the rings is visible in monochromatic than in white light, because the differently coloured rings, after a certain thickness of film has been attained, become superposed and reblended to form white light.

On Friday evening, May 14, Mr. W. H. Perkin, F.R.S., lectured upon "The Newest Artificial Colouring Matters," and confined his attention principally to the coal tar colours. These, he said, are all organic bases, and the first of them was introduced about thirteen years ago. He then entered into much of the organic chemistry of the coal tar colours. Among his experiments was one showing the great specific gravity of the vapour of benzole. He placed about a quarter of a pint of benzole in the bottom of a large cylindrical glass jar, and then placed a thick disc of warm iron in the benzole to raise much of it to the state of vapour. The vapour was then poured from the jar into a wooden trough, about 9ft. long, placed in a slightly inclined position. The invisible slightly inclined position. The invisible vapour ran down the trough and was ignited at the other end. Two very pretty experi-ments consisted in the exhibition of the fact that aniline pink and the colouring agent called "Magdala" are fluorescent to the green rays of the spectrum. On Saturday, May 15, Professor Seeley gave another lecture upon "Roman History"; and on Tuesday, May 18, Professor Grant continued his lectures upon "Stellar Astronomy."

### ELECTRICITY AND TELEGRAPHY.

UP to the end of last week, about 2,740 miles of the main French Atlantic cable, and all the shore ends, and the St. Pierre and the United States section, had been completed. The major portion of the cable was on board the "Great Eastern." The fore and main tanks are filled, and a small quantity remains yet to be coiled in. whole of this cable, by the time this is before our readers, will have been completed at Greenwich. The following vessels, as cable ships, will be engaged in the expedition:—The "Great Eastern," "Scanderia," "William Cory," and "Chiltern." The landing place in the United States has been fixed, and steps are being taken for the construc-tion of a land line to New York.

Mr. Newall has just succeeded in laying a short cable between Corfu and Santa Maura, and is engaged in laying some other short lengths in the Grecian Islands.

The joint direction of the Atlantic and Anglo-American Telegraph Companies have issued a notice that after June 1 a reduction will take place in the charge for messages. They will then be at the rate of £2 per message of 10 words, charging for address and signature of sender, and for every additional word, at the rate of 4s. A reduction will also be made in general "Press" messages.

In laying the submarine cable between Born-holme and Liban, a storm came on, and necessitated the cutting of the cable; but on the weather moderating, the laying of the cable was successfully completed from the "La Plata" without difficulty. The "La Plata" is on her way home. On her arrival she will take in at Woolwich the cable now manufacturing for the Peterhead and Norwegian line.

The cable just laid completes a direct commu-The cable just laid completes a direct communication between England and St. Petersburg, via Newcastle, by the cable laid last year by Mr. Newall to Denmark, and across the Baltic to Liban by the two cables laid by Mr. Henley. From Liban there is a land line to St. Petersburg. The Peterhead cable, just completed at North Woolwich, is 285 knots in length, and will be sub-

merged between Peterhead and Egersund, in Norway. Its weight is a little above 2 tons per knot. The conductor is a copper strand, of 180lb. to the mile, insulated with an equal weight of Hooper's india-rubber core. It is served in the ordinary manner, and sheathed with twelve No. 8 iron wires. Of the total length, 10 knots will be of stouter manufacture for the shore ends. This length will be sheathed with ten No. 1 wires.

French Atlantic cable manufactured by Mr. Henley, he has now in hand 52½ statute miles of cable for the Norwegian Government. The core of this cable consists of a strand of copper, 107lb. per mile, insulated with gutta-percha to the weight of 166lb., making a total weight of 273lb. per mile. The sheathing of this cable is 10 No. 6 iron wires. Mr. Henley is also manufacturing a length of 12 knots of 7-wire cable for crossing the Store Belt. Each wire has a conductor of 1071b., insulated with 126lb. gutta-percha. The external

protection consists of 16 No. 5 iron wires.

The British-Indian Telegraph Company have just issued their report. They state that the whole of the capital offered to the public has been subscribed, and that the order, with the first payment, has been given to the Telegraph Construction and Maintenance Company, who have already commenced the manufacture of the core at the Gutta-Percha Works, and, at the date of the report, 250 miles of core had been completed, while about 500 miles were in various stages of manufacture. The manufacture of the cable at the sheathing works at Greenwich had not been commenced, but it is most probable that, by the first week in June, a commencement will have been made.

News from Australia informs us that the paying out of the Tasmanian cable had commenced on April 22, but that a sudden gale had compelled the engineer in charge to cut and buoy the cable. Doubtless, the next mail will bring us satisfactory news of the completion of the work.

news of the completion of the work.

There is every probability of the "Telegraph Money Bill" being brought before the House of Commons at an early date. The arbitration case between the Post Office and Reuter's Telegram Company is now virtually over; the witnesses have been examined, and the counsel engaged made their concluding speeches. The matter is now, therefore, in the hands of the arbitrators and the umpire, and the award is expected in a few days. This being settled, there will, we underdays. This being settled, there will, we understand, be little further delay in completing the estimates for the amount actually required for the

purchase of the telegraphs.

ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL AP-PLICATIONS.

THE CARBURIZATION OF AIR FOR ILLUMINATING PUR-POSES-COAL TAR DYES.

LTHOUGH most of the attempts to procure f A illumination by burning air, saturated with hydrocarbon vapours, have resulted in failure, the many advantages of the plan are so obvious that inventors are certain to go on experimenting, and, in the end, no doubt, all difficulties will be overcome. The last "Bulletin" of the Societe Industrielle of Mulhouse, furnishes us with a report trielle of Mulhouse, furnishes us with a report on the carburetting apparatus of M. Andirain, with which a committee of the Society has experimented. Unfortunately, the committee has neglected to furnish us a description of the mechanism, but they have told us one thing, which perhaps explains the success. The carburetting liquid employed was a very light petroleum having a density of only 650—660. With this liquid, they found no condensation take place in having a density of only 650—660. With this liquid, they found no condensation take place in the pipes travelling 120 yards in the open air, and the illuminating power of the mixed air and vapour was sensibly the same at all distances from the reservoir of hydrocarbons. That this would be the case when very light oils are used, might be supposed, and there can be no doubt that the sole secret of success in carburetting air cas lies in the use of these materials. We or gas lies in the use of these materials. believe there is a great future for this application, and this belief induces us to stimulate inventors to produce an apparatus which will suffice to illuminate a large country house or railway station, where gas is not accessible. Carburized air has some advantages over gas for domestic illumination. The flame is never smoky, and, consequently, does not soil ceilings. The combustible destructive effects of sulphurous and sulphuric acids are avoided. And, perhaps, most important of all, the vapour forms no dangerous and ex-plosive mixture with air, if leakage should take place. For lighting railway trains, carburized air would seem to be peculiarly applicable, as the motion of the train could be made to furnish the blast, which a regulator could easily deliver at any desired pressure. Nor would it be less available for warming carriages in winter, in place of the cumbrous hot-water contrivance, which our rail-In addition to this cable and the portion of the way companies supply very parsimoniously. As

we have said, there is still a good field for inventors in this direction.

Anyone who listened to Mr. Perkins' lecture on the newest discoveries in artificial colouring matters would have been struck also with the large field there is still open for experimenters in this branch of science. Aniline itself does not appear to be yet exhausted, while other bodies are being pressed into the service of the chemist in producing these beautiful dyes. It has been a favourite speculation with some who have adopted Stephenson's notion that coal is but fossil sunlight—that coal tar products would be made to furnish all the colours of the sun's spectrum. The idea is almost realized, but we have a great predominance of red shades. We are reminded of this by reading of a new red, which is now manufactured here, and of which we do not remember to have seen any notice before. The description of the mode of production is, as might be expected, vague, but enough is said to put a chemist on the scent, and show the direction in which the latest discoverers are working. This new rose colour, which is said to give more solid dye than aniline compounds, is, we are told, obtained by the reac-tion of phtalamine on a derivative of napthylamine. This is not very specific information, but it will convey some instruction to a chemist; and the fact that the colour now sells for about £24 the pound may stimulate him to experiment.

In the lecture we have mentioned, Mr. Perkins told an amusing story of an inventor who produced an aniline green, which he was, however, unable to fix. In his despair, he went to a photounable to fix. In his despair, he went to a photographic friend, who, reasoning that since hyposulphite of soda would fix a photographic picture, it might fix anything, recommended the dyer to try that salt. He did, and found it succeed. Apropos to this, we read in the "Mulhouse Bulletin," before quoted, that aniline green is a compound of Hoffman's violets and iodide of mathyl. If the dye is heated in a scaled tube it. methyl. If the dye is heated in a sealed tube it

splits up into these two compounds.

One other fact we may notice in connection with aniline colours. The mixture which produces aniline black, when printed on cloth, it seems, rapidly corrodes the scraper, and unless this is well attended to blotched patterns are obtained. This inconvenience is partly avoided by adding some hydrated oxide of lead to the mixture; at all events, a larger number of pieces can be printed without paying attention to the scraper.

### THE MARTINI-HENRY RIFLE.

AST Friday afternoon, Captain V. D. Majendie, R.A., read a paper at the Royal United Service Institution upon the Martini-Henry rifle. Having referred to the early history of small arms, and to the recent changes in their construction, he came to the immediate subject of the paper. After reading an extract from the report of Ordnance Committee for 1862, he stated that the highest prize awarded in the competition which ensued had been adjudged to the Henry rifle the Martini weapon then standing seventh in the list. The inferior position of the latter was, however, attributable to defects of ammunition, copper fire cartridges having been used in its trial. Daw cartridge was then recommended. This was like the service cartridge, inasmuch as it consisted of thin coiled brass. Unlike the service cartridge, it was secured by soldering the edges instead of cementing them with paper fitted into the base. The whole subject then divided itself into two parts—the one regarding the common denominator parts—the one regarding the common denominator for barrels and the other concerning the method of loading. With respect to the barrel question, the superiority of the Henry rifle had been demonstrated by a preponderance of competent authority, as regarded trajectory, accuracy, initial velocity, and penetration. Other qualifications, he urged, were not to be postponed to those he had enumerated. rated. The Henry rifle, however, did not exclude any of these to which he had last referred. Re-garding loading, it was admitted that the operation should be performed at the breech. In this case mere rapidity was not the only thing to be considered. The durability of the breech mechanism. its simplicity, its safety, its ease of manipulation, its non-liability to injury by exposure or rough usage, were all important in directing opinion on the subject. In the competition to prove rapidity the following was the order of merit:—1, Westley Richards; 2, Martini; 3, Henry; 4, Westley Richards (equal); 5, Berdan; 6, Money-Walker. The exposure test, however, had reduced the competition to the Martini and Henry weapons. The parts in the latter were much more numerous

than those in the former, which was easier of manipulation and also somewhat cheaper. He then explained the construction of the rifle, which will be found illustrated and described in the MECHANICS' MAGAZINE for March 19 last. It consists of a swinging block hinged on a pin, passing through its near end, the recoil being taken by the shoe. The cartridge is exploded by a direct-acting piston, driven by the impress of a strong spiral spring within the breech-block. The moved by the action of a lever to rear of the trigger guard. The motion of pushing the lever forward depresses a block, compresses the spring, and ejects the empty cartridge. When the lever is drawn the block is raised and the breech closed.

Captain Majendie then observed that in the Martini-Henry rifle the advantages of both the separate weapons had been combined. The following argets had been obtained at the following distances:
—300 yards, '47ft.; 500 yards, '79ft.; 800 yards,
1.29ft.; 1,000 yards, 2.19ft.; and 1,200 yards,
2.28ft. He then answered several of the objections made to the adoption of the new rifle. He denied that the face of the block was convex, as alleged by those who condemned it. He also replied to the assertions that if the trigger were full before the block was closed it would fire the cartridge, and that the empty case would be ejected into the face of the rear rank men. In answer to the objection opposed to the use of the spiral spring, he said that this contrivance had been adopted by the French and Prussians, and it was the only part of the Chassepot and needle guns which was not to be altered. Two hundred Martini-Henry rifles would be ready before the Wimbledon meeting this year, and the Enfield plant would be converted at the rate of 400 a-week. The bayonet to be employed with the rifle was the saw bayonet, which was at present used by the Royal Irish Constabulary. This would be useful not only as an ordinary bayonet, but also as a saw and a couteque de chasse.

### THE PROPOSED ABOLITION OF PATENTS.

OUR readers scarcely require to be reminded that just before the Whitsuntide recess, Mr. Macfie gave notice in the House of Commons of his intention to move, after the recess, a resolution, declaring that, in the opinion of the House, the time had arrived when the interests of trade and commerce and the progress of arts and sciences would be promoted by the abolition of patents. In consequence of this mischievous intention on the honourable gentleman's part, Tuesday last a deputation of members of the Inventors' Institute, the delegates invention right committee, and other gentlemen representing numerous industrial associations, composed as follows:—Captain J. H. Selwyn, R.N., vice-president lows:—Captain J. H. Selwyn, R.N., vice-president of the Inventora' Institute; R. Marsden Latham, George Potter, T. Paterson, F. W. Campin, T. J. Dunning, B. Walker, G. F. Savage, J. Hasleton, B.A., and George Druitt, waited on the Attorney-General, as one of her Majesty's acting commissioners of patents for inventions, to solicit his attention to Mr. Macfie's proposed motion in the House of Commons for the abolition of patent rights for inventions. The members of the deputies in processed ways that Attention General, that tation impressed upon the Attorney-General that the interests of the working classes and the status of the country, in regard to the mechanical and chemical arts, would be greatly injured by the abolition of the patent laws, although they unani-mously required that these laws should be simplified and rendered more efficient. The Attorney-General gave every attention to the deputation, and expressed his general concurrence in the views put forward by them, but stated that he did not yet know the policy of the Government on this question, although he individually was opposed to Mr. Macfie's motion. We are certain that such an absurd motion will find but few—if any—supporters in an assembly like the House of Commons. Such potions are not to be talemted. Commons. Such notions are not to be tolerated in the present day. We reserve further remarks upon this question until such a time as the matter is fairly before the country.

The following are the reasons why Mr. Macfie's motion should be negatived in the House of Commons, as submitted to the Attorney-General

by the deputation:-

1. It is the duty of the State to encourage in-

skill, equally as much as the author or the artist is entitled to copyright for his book or work of art.

3. That the patent system, though defective, is the best practical method of remunerating inventors yet devised, inasmuch as under it those persons only who use inventions, and to whom, therefore, they may be assumed to be of service,

4. Experience shows that no system of rewards from the State could ever be made to work satisfactorily, either in the interests of inventors or the

public.

5. The inventor, as distinct from the manufacturer, has a right to be heard before the patent laws are abolished or materially altered.

6. Inventors and specially those belonging to the working classes, to which classes the great majority of inventors belong—are entirely opposed to the abolition of the patent laws, though they earnestly desire their amendment.

7. That by a good system of patent law the progress of the trade and industry of the country would be largely benefited, as the whole inventive talent of the nation will be thereby incited to strenuous and continued efforts to maintain our industrial position against the very active pressure of foreign competition now affecting our commercial prosperity.

8. That working men, who are largely represented by the present deputation, are especially anxious to find themselves in a position, under an amended patent law, in which they can not only safely exhibit their inventions in public, but be enabled to reap the fruits of improved education

and increased application of invention,

# PHENOMENA OF MAGNETIC STORMS.

R. R. H. ALLNATT recently addressed some MR. R. H. ALLNATT recently addressed some remarks to the "Times" upon the clouds in connection with magnetic storms. He says some five or six years ago the Astronomer Royal, Mr. Airy, laid before a meeting of the Fellows of the Royal Society a theory to account for the phenomenon of magnetic storms. "These phenomena," he says, "represent the movements of a magnetic ether which overspreads the surface of the earth as an impalpable fluid envelope several feet in thickness." If we imagine this magnetic ether to be subject to impalpable find envelope several reet in thickness."

If we imagine this magnetic ether to be subject to occasional currents produced by some action or cessation of action of the sun, which currents are liable to interruption or perversion of the same kind hable to interruption or perversion of the same kind as those in air or water, we have a theory by which the disturbances that occur in the observed phenomena by terrrestrial magnetism may be explained. "It would be well," says the late Professor Nichol, "to discuss magnetic observations more from a meteorological point of view than has hitherto been done."

done."

Let us, then, take the clouds, about the specific modification of which so little is known. During the past month a diligent observer might have witnessed the following phenomena:—A thin, apparently homogeneous body of vapour has been driven rapidly up by a S.W. wind, and on approaching a certain well-defined spot about two points N. of N.W., and of about 10deg. of elevation from the horizon, has assumed a succession of ponderous radii, like a huge expanding fan, stretching beyond the meridian. On the 18th these radii co-existed with a vivid aurora, and according to Mr. W. H. Preece, with very strong intermittent earth currents on all long telegraph circuits in the S. of England.

Last night (17th), at 24min. after indigint,

Last night (17th), at 24min. after midnight, another beautiful example occurred. A thin lenticular another beautiful example occurred. A thin lenticular cirrostratus gain bore up rapidly from W.S.W., and on reaching the spot indicated (N.N.W.) assumed a succession of opaque radii with illumined interspaces. The N. horizon was clear. These perpetually recurrent radiating overcloudings are a mystery. They have more effect upon the needle than tempests themselves. The question is, are these peculiar forms of condensation the cause or effect of the magnetic perturbation? Colonel Sabine says that the perturbation is the effect, and that it is a purely magnetic fact, the explanation of which depends on that of the physical cause of solar and terrestrial magnetism. All the phenomena hitherto known of the diurnal magnetic variations have been explained magnetism. All the phenomena hitherto known of the diurnal magnetic variations have been explained by supposing that the sun acts upon the earth as a very powerful magnet at a great distance. When will the "experimentum crucis" be made?

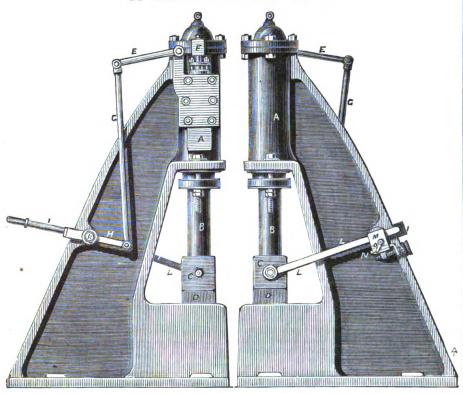

M. MEGE-MOURIES states that brown bread is a compound of coloured matter, produced by the action. of a ferment he calls cerealine. By preventing the action of this ferment, brown bread is converted into vention by every legitimate means, in order to enable this country to maintain its supremacy in mechanical and chemical arts.

2. That the inventor is entitled to reasonable remuneration for his labour, expenditure, and

# SINGLE-STANDARD SELF-ACTING STEAM HAMMER.

BY MESSRS. J. BARRANS AND CO.

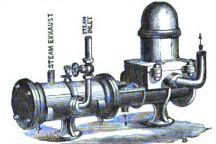

### SELF-ACTING STEAM HAMMER.

THE annexed engraving represents two views of a very neat single standard self-acting steam hammer, by Messrs. J. Barrans and Co., of the Steam Hammer Works, Whitehall, Sheffield. A is the cylinder, B the piston rod, and C the tup, which is forged solid at the end of the rod, D is a loose anvil block, which fits into the standard, E is the valve lover, one end of which works through the valve lever, one end of which works through the valve spindle F, and the other end is connected by the rod G to the lever H, which is worked by the handle I when working by hand. When working self-acting, it is fastened by a steel screw at the under side of the boss to the die box shaft K, which passes through the hammer side, working in two bosses, cast on for the purpose. L is the tup lever which works on a steel pin through the tup, and passes through the adjusting box M, and thus gives motion to the valve as the tup rises and falls. It is adjusted by means of the wedge N, by which adjustment the travel of the valve is varied, thus altering the weight of blow and length of stroke as required. The small handle O holds the die in position when adjusted. These steam hammers are already in use at more than a score of engineering works, where they are giving every satisfaction, and the manufacturers are constantly receiving new orders.

# STEAM PUMPS.

N American invention of considerable interest has lately been introduced into this country by Messrs. Hayward, Tyler, and Co., of Upper Whitecross-street, in the shape of a steam pump. It belongs to the class in which there is no rotating motion. In this particular, however, there is nothing especially new, there being many pumps working without flywheels or crank shafts. The chief point of novelty in this instance consists in the extremely simple method of working the slide valve without the aid of cams, spring valves, levers, tappets, &c., the use of which in most cases has been a source of trouble and annoyance. In this case the reciprocating motion of the piston is case the reciprocating motion of the piston is effected in a very simple manner, though, owing to the working parts being within the piston itself, it may not appear so at first sight. The piston is elongated to about the length of its stroke, and contains within it a cylindrical slide valve, which, together with the piston itself, contains steam, supplied to it by a slot on one side of the piston. In the main cylinder are placed ports correspond-

ing to others in the piston. These are so arranged that when the piston arrives nearly at the end of that when the piston arrives nearly at the end of its stroke, by the ports coinciding, steam is ad-mitted to one end of the cylindrical slide valve, causing it to change its position to the opposite end of the main piston, and by this means reversing its motion. The same thing occurs when the piston reaches the opposite end of the cylinder. It will be seen that no parts come in contact with each other, the whole being effected by one port passing over the other. The motion thus produced is steady and perfectly noiseless the speed of the steady and perfectly noiseless, the speed of the piston varying from 10 to 300 strokes per minute.

It will thus be seen that there are only two moving parts in this machine, which is represented in the

above cut.

The whole being self-contained, no bed-plate is requisite. Moreover, as all the working parts are covered, this engine can be placed in dusty places where machinery having bearings, pins, joints, &c., would soon be destroyed. The only visible moving part is about a couple of inches of visible moving part is about a couple of inches of piston rod, passing between the steam cylinder and the pump. The valves of the pump are also well arranged, being on a flat surface under the air vessel, by the removal of which they are accessible without breaking any pipe joints whatever. We recently paid a visit to the works of Messrs. Hayward, Tyler, and Co., where we saw one of these pumps at work, and were much pleased with its action. It worked equally well at slow and quick speeds. Taken apart, the simplicity of the action is at once apparent, although it must have exercised the ingenuity of its inventors—Messrs. Cope and Maxwell—to perfect it. In the United States, we understand, there are a great number of these pumps in use; this cannot fail to be the case these pumps in use; this cannot fail to be the case in England when its merits become known. A working model of this pump was exhibited at the conversazione of the Institution of Civil Engineers last Tuesday evening.

### AERONAUTICAL SOCIETY OF GREAT BRITAIN.

A GENERAL meeting of members was held in the rooms of the Society of Arts, on Thursday evening, the 20th inst., for the reading and discussion of papers. The chair was occupied by Mr. Glaisher, F.R.S.

The Chairman said he was sorry to have to announce that the Duke of Argyll was unable to take the chair, as he would have done, had this meeting taken place during the time he was in London; but, considering how oppressed he is with work, they would not begrudge his Grace his journey to Scotland. It was now a long time since the Society had met, but from the nature of its objects, viz., to obtain aerial navigation, they could scarcely expect that their meetings should be frequent, and they were by no means anxious that they should be frequent. The subject was entirely dependent on experiment. Theorists and mathematicians told them what to do, but practice proved that theorists do not agree. Experiments must be carried out by mathematicians, with the aid of physical science, or they could not hope to succeed. At the present moment, a number of gentlemen were engaged in these experiments, but from the requirements of other duties, they had not much time to

devote to them.

To these he might say "go on," for, although they might not have much effect in one time, he never found, in his experience, but that some good followed from continued experiments. They should never forget that Sir William Herschel, when he discovered double stars, was first engaged in attempting to ascertain their distance from the he soon found this indication to be fallacious; yet, starting from this error, he was quickly led to the discovery in question. So he believed that experiments inaerial navigation would increase our know-ledge, one way or another. They met that night under peculiar circumstances, there being in London at this time the largest balloon yet made. The original discovery of the balloon was due to France, and to the enterprise and courage of Frenchmen they were indebted to the balloon now at Ashburnham Park. M. Giffard had selected for management persons in whom he had confidence, one of whom was M. Godard, and he had placed the balloon at his (Mr. Glaisher's) disposal, to use in any way he thought proper, to increase aeronautical knowledge. They had there an opportunity, such as they never had before, to take observations, and he was sure that the members of the Society would avail themselves of a visit to Ashburnham to see this balloon. selves of a visit to Ashburnham, to see this balloon, which was made strong enough for rising under different forces of wind. That balloon had spoken to him trumpet-tongued. All his life he had been accustomed to weigh the air, and he had weighed it by a barometer, and in a balloon, and always by grains, and in winter he found the cubic foot to be about 570, and in summer 20 or 30 grains less; but when they took grains, they thought the air light. When he saw, the other day, that the balloon would lift 16 tons, or more, and when against the laws of gravitation it could raise so much, there must, he thought, be something for members of the Society to study. When they looked at the fact there are 420,000 cubic feet of gas in the balloon, they would see what was the motive power; he trusted they would have some papers of interest that night, but if they were to be progressive, though it might be slowly, it must be by experiment.

Mr. Frederick W. Brearey said he would first-ead the following communication from Captain Murray, R.N., one of the members :- "In enclosing my subscription for the current year, I would ing my subscription for the current year, I would suggest that, as at present, the Society and its members are groping in the dark, for want of any knowledge of the fundamental relation between pressure and velocity of air. They should offer a substantial prize—of not less than £100—for a complete and general solution or rigid mathematical principle of the following problem:—'Required, the relation between the velocity of a current of air and its pressure on a plain surface of given size, shape, and inclination.' Should the Society see fit to adopt the suggestion, I will contribute £10 towards raising the necessary fund. The £10 towards raising the necessary fund. The problem is one of exceeding difficulty, but there are, probably, a dozen men in the country competent to apply to it the most subtle method of modern analysis, with a fair chance of success; and, when solved any one of groad recebusical country. when solved, any one of good mechanical capacity will be able to say at once what can and what-cannot be done in the way of flight. For my own part, I have little doubt that the result will show that the power of a man can be so applied as to

sustain himself and his apparatus—weighing (say) 200lb.—at a high speed. I have attempted the problem myself, but the result has been to satisfy me that it is a hopeless task for any one not gifted with the very highest mathematical capacity to attack even the simpler cases of it. It seems to me that for the Society really to further the great object which they have in view, they must attack this problem either as I propose, or experimentally, at a great expense, and with less certain results."

The Chairman said that no doubt Captain

Murray was quite right in his views upon this matter, for they knew that the mathematical problem connecting velocity with pressure had to be solved, yet it was found by experiments that results did not quite accord. If they took a square inch of surface and a square foot of surface with the same velocity they did not get the same results. It was in this direction they required experiments to be made. Perhaps Mr. Brooke, who had paid great attention to this, would say some-

thing upon the subject.

Mr. Brooke, F.R.S., remarked that the fact is lost sight of, that when velocity of an opposing surface has done its work upon the air, this has to get out of the way, and that would much depend upon inclination of surface. This, he thought, was

not thoroughly understood.

Captain Murray said that the problem he had 80.000 sted had never really been attacked. actually worked out it would be found that theory and experiment correspond. No theory would say that the pressure on a square inch is the same

as the pressure on a square foot.

M. de Fonvielle (editor of "La Liberté") suggested that the pressure and velocity of wind can be obtained by the use of an anemometer in the captive balloon, by deducing the force on a plain surface from the known difference of result on a sphere, to which figure the balloon in question closely approximated.

The Chairman said he intended to consult Mr.

Zambra on that point.

Mr. Quartermaine said he saw no more difficulty in estimating the pressure of the air than in cal culating the pressure upon a steam boiler. At the same time, it should be borne in mind that in aerial navigation they had to deal both with resistance and with the air following up.

Mr. Olrick said that no doubt a number of ex-

periments are required to determine velocity and pressure, as it is found that various theories on the subject are not substantiated. With regard to aerial navigation, it should not follow that, as Scott Russell pointed out, the wave line is the best for a ship, the same line should be best for aerial machines. He cited his explanation of the ingenious contrivance in Giffard's injector, the action of which many engineers had attempted to explain, and he submitted that his formula on that invention agreed with practice.

The Chairman said he did not say that pressure and velocity are not connected. Doubtless, they are; but in the experiments at Greenwich they vere unable to connect them; and when Mr. Scott Russell and he tried the results of the two, they

were not identical.

Mr. Thomas Moy spoke upon the relative power and surface in mechanical flying machines with mathematical diagram for computation, upon the thrust of aerial screw propellers, and upon the flight of the albatross. He prefaced his remarks flight of the albatross. He prefaced his remarks by reading an extract from a book by Wilkins, Bishop of Chester, published in 1683, in which the right reverend prelate stated his belief that an aerial chariot might be made by a man who had leisure enough, on the same principle as Archytas made a wooden dove, and Regiomontanus a wooden eagle. This extract Mr. Moy urged as evidence that a belief existed, at that early that a wooden dove and a wooden eagle had been made. Mr. Moy then explained to the meeting a diagram which he had prepared for calculating the proportion of sustaining surface in relation power for mechanical flying machines. The table showed, in a very simple manner, how many square feet of surface would be required to sustain a machine of 100lb. weight, beginning with 1-horse power to that weight, and going as high as 4-horse power, the amount of surface being readily seen as represented by a curve of the hyperbolic order, and the pressure per square foot being shown by another curve. He remarked that he thought this table would be quite sufficient for present purposes, as it was not likely to be exceeded in either direction for some time, the lowest power being, according to this calculation, 1-horse power —1,455 square feet of sustaining surface, and 1-1oz. (loz. and 1-10th) to the square foot; and the highest being 4-horse power—91 square feet,

and 17 to the foot per 100lb. weight. table being drawn to scale, any intermediate calculation between these two extremes could be obtained by simply drawing a parallel line across the proportionate power in the column for horse power, and continuing such line across the two The thrust of the screw propeller was Mr. Moy's next subject, and he remarked that the analogy between a ship and an aerial machine was not so close as many persons seemed to think. A screw steamer on starting from a state of rest exerts but a very small proportion of her power, and only obtain the total effect of her power when at full speed; but the aerial machine requires the exertion of its full power at once, in order to rise. This he explained by showing the thrust at different angles to sustain 100lb. :posing, first, that the angle is 45deg. to start with and the speed 10 miles an hour, the thrust would be equal to the load, 100lb.: but as it gathers way the thrust decreases, and when going 17 miles an hour, the angle would be reduced to 30deg., and the thrust to 58lb. Going on again to 27 miles an hour, the angle would be reduced to 20deg., and the thrust to 36.71b.; and still further incre the speed to 59 miles an hour, the angle would be 10deg., and the thrust only 17lb.; and in each instance the power exerted is the same, but the mode of applying it varies, for at first starting a powerful thrust is required at a comparatively low speed, but afterwards, when in rapid motion, a light thrust at a high speed; whereas, in the case of a ship, a small amount of thrust is sufficient to put her in motion, and the thrust increases with the speed. Mr. Moy next gave an explanation of the modus operandi of an albatross scaring over the waves of the sea for many miles, without any apparent effort on the part of the bird. He mentioned the fact that the waves are caused by the wind impinging upon the surface of the water. The wind, as it were, attempting to travel in a straight line, is deviated therefrom by the earth's globular form, and thus, impinging at a tangent, the wave is caused; and the greater the force of the wind, of course, the greater must be the body of water heaped up to shunt it upwards. This imparts to the wind just above the waves a wave motion, and Mr. Moy considered that the bird soared across the valley of the wave, and when it arrived over the apex, it got just what it wanted without any exertion, viz., a small upward current of air sufficient to lift and propel it to the same extent as a beat of the wings would do in a straight current. Lastly, Mr. Moy closed his remarks by observing the difficulties which model flying machines laboured under. He said that if we attempt to make a small model to scale of the "Great Eastern," the cylinders, &c., would have to be as thin as paper, which would impossible, and unless the scale could be kept throughout, the proportionato results would not be fair; and if that meeting had been convened in order to show by model, for the first time, the practicability of working rail-ways, the proportionate results would not be in the least expected. We know that a locomotive engine can draw a load equal to ten times its own weight, but the model locomotive would satisfy us if it drew only a load equal to itself, and no one would on that account deny the practicability of railways. But with the model flying machine no 10 per cent. will suffice; it must lift the last ounce, or it is pronounced a failure. If it resists gravitation 10 per cent only it is laughed at; it must fly, or it is nothing. This demand requires a higher perfection in the model than in the actual machine, and Mr. Moy stated that to him the actual steam flying machine would be very much easier to construct than the model. Mr. Stewart Harrison expressed his doubts as to

the reliability of some of the theoretical calcula tions of the reader of the paper, and stated his impression that chemistry might help us to as tain approximatively the amount of force expended by birds in flight. If, for instance, a man asserted that he had walked a thousand miles, and, during that time, had only been sustained by the consump tion of half-a-quartern loaf, the statement might fairly be doubted. No force could be exerted without change and destruction of muscular tissue, and the amount of force expended could be measured by the waste of the body exerting that force. therefore, during the emigration of wild ducks and other birds which passed over hundreds of miles in their flight, they exerted anything approaching the theoretically calculated force, they must have expended enough muscle to use themselves up nine or ten times over. He therefore concluded that the power exerted in flight was much smaller than usually supposed, and suggested the possibility of experiments on the waste of the

bodies of birds, to ascertain the amount of force actually expended during a given flight. Assuming that much less power was required than was usually supposed necessary, he stated that hitherto, as far as he was aware, all flying machines had been attempted to be worked by the arms. He considered that the legs in man could exert a much greater furce continuously than the arms; and expressed his opinion that a machine of the nature of a velocipede might be constructed with an aeroplane to act as a plane. This, with a speed of twelve miles per hour, would relieve the wheels of some portion of the rider's weight. Further, he would not be provided in connection with the few wholes. would provide, in connection with the fore wheel, a pair of propellers, with their long blades like the wings of the albatross in shape, turning in con-trary directions on each side of the rider in the position of wings, so as to prevent the tendency to twist round on the part of the whole machine, which would exist were one propeller only pro-vided. These would be so placed as to give a for-ward movement to the machine, as well as a slightly upward movement. He advocated the propeller form, inasmuch as he believed that all experiments hitherto tried had been with propellers, attempting a vertical ascent, the axis being in the line of motion—a condition which was widely different motion—a condition which was widely different from that of a propeller travelling through the air at a rate of ten or twelve miles an hour, and therefore exerting its force against a fresh and undisturbed column of air at every evolution. The failure of propellers attempting a vertical ascent was to be expected by the analogy of wings, for were a strong flying bird like a wild duck released at the bottom of a large chimney shaft, it would never reach the top by vertical flight. In conclusion, he expressed his firm conviction that a practised gymnast would be able to raise himself a practised gymnast would be able to raise himself from the ground on a velocipeds by the combined agencies of the original speed, the aeroplane tail, and the propeller wings. If he did not succeed in raising himself, the experiment was well worth trying, in order to see how much of the rider's weight was taken up by these agencies, and thus acquire data for further experiments with forces greater in proportion to their weight than that of the muscles. He, however, fully believed flight was possible to man by the agencies he had named.

Mr. E. W. Young, referring to Mr. Moy's remarks concerning the assistance which he assumed the ablatross derived in its flight from the upward current of air produced by the glancing of the wing from the slope of the wave, stated that he had observed the albatross skimming the ocean in all directions, with the wind, as well as against it; but that if Mr. Moy's hypothesis was correct, the albatross should be able to soar easily only when going against the wind. In the second place, he recommended that Mr. Stringfellow, whose apparatus he considered the most promising yet before the Society, should fly his model in a high wind as he would a kite, but with a horizontal string. He might then set his propelling apparatus to work, and if his model was able to advance against the wind, so as to slacken the string, mechanical flight would be accomplished without risk to the model.

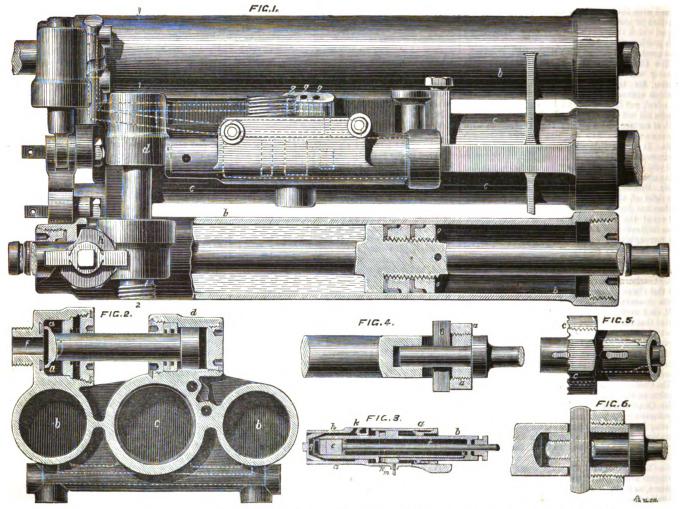

Mr. Young stated that during the summer he had made some rough experiments upon the lifting effect of the wind upon an inclined surface. apparatus was furnished with a vane working on an universal joint, to show the exact direction of the current of air, as the current of air seemed to move in waves over the surface of the ground, and that he had noticed the pressures at those movements when the vane was horizontal. This was a very necessary precaution, especially when dealing with a vane inclined at a small angle with the horizontal. He also stated, for the encouragement of others to make further experiments, that he had found, with a vane inclined at an angle of 12deg. with the horizontal, that the vertical lifting effect of the wind was about one-half the pressure which it exerted against the same vane placed vertically, i.e., if the wind were blowing with a force equal to 11b. per square foot against a vertical surface, it would exert a lifting effect of \$1b. per square foot on a surface inclined at an angle of 12deg. with the horizontal. This was merely approximate, but it was what might have been expected from careful observation of the flight of birds. He had, with the assistance of a mechanical friend, designed a more delicate apparatus for making the same kind of experiments, which he hoped at some future day to complete. and he believed that it would be found that mechanical flight by man could be effected without the necessity of such great speed as some antici-pated.

(To be continued.

# ROCK-BORING MACHINERY.

BY MR. F. B. DOERING.

# ROCK-BORING MACHINERY.

MR. F. B. DOERING, of Victoria-street, Westminster, who has taken a leading part in the development of rock-boring machinery, has recently patented some further improvements in this apparatus. The first part of his invention in engines of this class relates to means of regulating the forward movement as the work progresses of the main cylinder in which the piston carrying the tool works. In our engraving, this part of the invention is represented in longitudinal elevation, partly in section, in fig. 1, and in transverse section through the line 1—2 of fig. 1 in fig. 2. It mainly consists in regulating by means of a piston valve a, the supply of water or other fluid to, and the outlet of such fluid from, a pair of cylinders b b, attached to the main cylinder c, the valve a being worked by a piston in a cylinder by motive fluid distributed from the main cylinder to the small cylinder d, the piston of which is connected to the valve. Instead of attaching the adjacent cylinders to the boring cylinder, the pistons of these cylinders may be attached to the working or boring cylinder, the adjacent cylinders in this case being fixed. The adjacent cylinders b b have each a fixed piston e, and a supply of compressed air may be maintained at the front. So much of each of the cylinders as is behind the piston or pistons is filled with water. A tube connected at f leads from the piston valve a to a reservoir containing this water or fluid.

The action of the engine is as follows:—Supposing the main cylinder c and adjacent cylinders b b are at the back end of their travel, whenever the tool as it continues to work has cut to a sufficient depth to allow the main piston to uncover a port in the main cylinder communicating with the cylinder of the piston valve a, this valve moves and allows part of the water in the adjacent cylinders b b to escape under the pressure of the compressed air on the other side of the fixed pistons e e, or under the pressure due to the weight of the machine if the same is working downwards. The adjacent cylinders and main

cylinders are thus caused to advance, and this advance takes place intermittently according to the quantity of water which escapes from the valve until they reach the forward end of their travel. A cock at the front part of the adjacent cylinders is then opened to let out the compressed air, and pressure is exerted on the water in the reservoir to force the water through the valve into the adjacent cylinders, the small cylinder d exhausting into the main cylinder to allow the valve a to be moved by the pressure of the water, the piston of the main cylinder being put into the required position. The pressure of the water in the adjacent cylinders causes them and the main cylinder c to run back on their supporting bars to recommence their forward travel; the valve a is then closed, the cock at the front end of the adjacent cylinders is reversed, and the pressure in the water reservoir is removed.

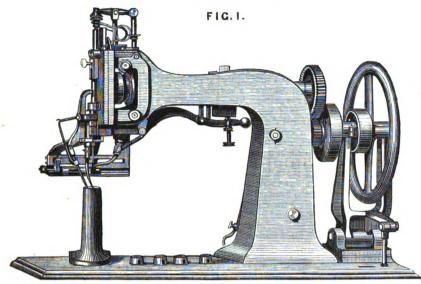

When the engine is working vertically or nearly so the employment of compressed air in the adjacent cylinders may be dispensed with, as the weight of the engine will be sufficient to effect the feed as the tool cuts. Again, instead of compressed air in the adjacent cylinders, a vacuum may be created in the water reservoir connected with the valve. This application of water to regulate the advance of a boring engine may be applied directly to the advance of the boring tool, as shown in fig. 3, the cylinder a being stationary and the piston rod b forming a cylinder in which a piston c attached to the boring tool moves. Water is placed in the front portion of the piston rod at f, and a pressure of the motive fluid acting on the back of the piston at g being constantly supplied through b to keep it pressed against the water so as to advance when the water or a portion of it is discharged through b. In this case, the valve for the discharge is formed by the piston. This discharge can only take place when the tool has penetrated to such a depth as to allow the port b to communicate with b. A circular groove is cut in the piston at b to regulate or adjust the engine for working in materials of different hardness or softness.

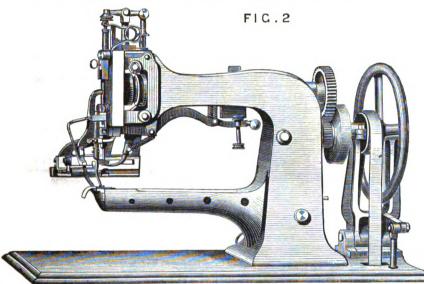

The ports g g g in the main cylinder are formed at various distances from the cylinder end, and communicate with the passage leading to the advance cylinder d through a cock common to all these ports. According to whether the material operated upon necessitates a short or long stroke, the cock is turned to open the way between the advance cylinder and one or other of the ports to produce the advance of the engine when the main piston has passed this port in its stroke. Instead of employing a cock common to all these ports, Mr. Doering provides plugs by which he can close all the ports except the one required for work. It is also sometimes desirable to alter the position of the ports in the main cylinder for working the valve; this may be effected by a cock h arranged similarly to that before described, or the communication between the cylinder and its valve piston may be throttled or wire-drawn.

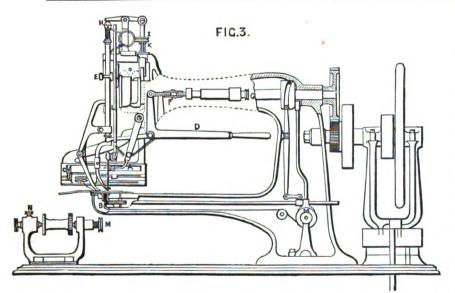

Mr. Doering's invention consists, secondly, in an improved mode of securing the tool in the end of the piston rod. For this purpose he threads the end of the piston rod or socket, as represented in fig. 6, to receive a nut a, and makes the position for the ordinary key b adjustable. He screws up the nut a, and then drives in the key which jambs against it. He thus compensates for wear, and is enabled to dispense with washers as usually employed. In some cases he forms grooves in the nut as shown at c, fig. 5, to receive the edge of the key. The nut is thus prevented turning. He can also employ a nut on the inner end of the tool head, as shown in fig. 6, and can also form the rod of the main piston hollow, and pass the tool down it, securing it by a nut and key, as shown in fig. 5. A model of this machine was exhibited by Mr. Doering at the conversazione of the Institution of Civil Engineers last Tuesday evening.

THE gold medal for physical geography, offered by the Royal Geographical Society to the great schools of England and Scotland, has this year fallen to Rossall, and has been won by Mr. William Grundy, who was for five years at St. John's Foundation School for Sons of Clergymen, at Clapton.

## "CRISPIN" BOOT AND SHOE THE MACHINES.

THE "CRISPIN" BOOT AND SHOE MACHINERY.

FROM the earliest times down to the present the occupation of the shoemaker has been carried on by him while sitting on a low stool. It was in this position that a sandal maker was represented in a painting discovered on the walls of Thebes. It is in this position that the disciples of St. Crispin are, for the most part, to be found working in the present day. How much longer

this cramped and unhealthy position is to be re-tained throughout the trade we cannot say, but before we close this article we shall show that if

many departments of manufacture, and that instrument has been the means of lightening the labours of the working bootmaker. It first helped him in the tedious operation of sewing together the leather for the uppers—technically called "closing." Next, the upper was attached to the sole by the same means. This was in 1859, when a Mr. Blake patented in England an improvement in the Wiskersham sewing machine, an American invention. invention. The upper, however, was attached directly to the sole without the intervention of a welt, which resulted in a very rigid boot which wa very difficult to repair. It is true, we have had riveted and pegged and screwed boots, but, being easily made, the work was often entrusted to boys, who produced anything but comfortable boots and shoes. The riveting, also, was difficult to repair, re-soling meaning almost re-making.

It therefore followed that boots were almost universally made by hand, at considerable cost to the purchaser, and without any relief to the producer from the uncomfortable and cramped posi-tion in which he was obliged to work. This con-dition of things led Mr. John Keats, of the London Mills, Leek, Staffordshire, in conjunction with Mr. W. S. Clark, in 1863, to design a machine which should admit of the use of two threads, waxed with should admit of the use of two threads, waxed with shoemakers' wax, and which should, in fact, manufacture welt sewn boots, equal in quality to hand sewn, although less in price. This invention, in conjunction with a patent taken out in the same year by Messrs. W. and J. Keats, forms the basis of the "Crispin" sewing machine, which, in its perfected state, we have illustrated in the annexed engravings. The leading features of this machine are the computation of a book and a shuttle instead of a needle bination of a hook and a shuttle, instead of a needle and a shuttle. This arrangement allows of the thread being thoroughly saturated with the wax, which does not get squeezed out, as in passing through the eye of a needle. Further, the hole made in the leather is no larger than the ize of the hook, because it has no thread in it while piercing the material. Thus, a thicker thread can be used than with the needle. The stitch, which is formed on the surface of the leather, is a twisted lock stitch, one of the firmest made. The machine is arranged to be driven by steam power, and the

is arranged to be driven by steam power, and the motion can be instantly stopped by a foot lever at any point of the stitch, so that the workman has the free use of his hands.

We have illustrated the Crispin machines in our engravings. Fig. 1 is a perspective view of the "post Crispin," which is used for boot sole sewing. Fig. 2 shows the "arm Crispin," which is employed in heavy work, such as closing heavy uppers, belt-sewing, harness work. &c. This machine is shown sewing, harness work, &c. This machine is shown in section at fig. 3, which gives a clear view of its details. The modus operandi of this apparatus will be seen from the following. The hook is first fixed by turning the machine by hand until the line cut across the edge of the needle bar l at the lower end (pointed at by the arrow) is on a level with the bottom end of the slide, and then fixing the hook with its point on a level with the point of the divider a, care being taken to have the notch which receives the thread at right angles with the arm of the machine. After the large bobbin is charged with thread and placed in position, the cover and hook plate at the end of the arm are drawn off, and the thread brought over the guide pulleys until it reaches the pulley b; it is then passed through the eccentric hole in the small gear wheel. The thread is then drawn forward and passed through the hole in the drawn forward and passed through the hole in the hook plate, the cover and plate being replaced. To thread the shuttle, the bobbin has to be placed in it, with the long centre end foremost. The thread is then passed through the upper slot over the bar and through the lower slot, and then through one of the round holes. The operator then places the shuttle upon the slide, and puts down the hinged stop c. He raises the pressure foot by means of the lever d, and puts the work under the hook so as to be moved from left to right. After the machine is charged with waxed thread, the gas is turned on, and lighted through the holes in the side of the arm, and also the jets behind the shuttle race, until the machine is sufficiently warm to make the wax soft, care being taken not to let the flame come in soft, care being taken not to let the flame come in contact with the casting, as this produces soot, which destroys the heating power of the gas.

A counter-shaft mounted in the frame under the table being put in motion by the driving belt, the machine is started by pressing the foot lever, there-

before we close this article we shall show that if retained for any unreasonable length of time from the present, it will only be due to blind prejudice and wilful obstinacy. This change is simply the result of the application of machinery in a direction where it has long been wanted, but where, up to the present time, at the best, it has been but partially and imperfectly applied. The invention of the sewing machine was the signal for relief to

and kept to push in the required direction by the round vertical bar being pinched with the thumb screw e; an angle of 45deg. to the arm is found most convenient. The pressure is adjusted to the thickness of the work by means of the double screw nut f. The amount of pressure is adjusted by the screw g. The feeder is adjusted to the thick-ness of the work by turning the screw h. The length of the stitch is regulated by turning the screw i, which is secured by the lock nut k. To remove the large bobbin, the pin n is taken out tension spring then forces it out.

The inventors first commenced to use their machine for closing heavy uppers, afterwards it was resolved to make welted sewn boots. veloping this manufacture, a series of important improvements were introduced by Mr. Thomas Greenwood (of the firm of Greenwood and Batley, of Leeds), and Messrs. Keats, patents for which were obtained in 1866 and 1867. Since that time, the system of machine-made boots has been practically developed in the works of Messrs. Keats, at London Mills, and it has now attained to perfect success. We can ourselves testify to the of the work, having given both light and heavy boots made by the Crispin machine a fair trial. The work stands, they wear well, and are much more comfortable than some hand-made boots we have in ordinary wear, whilst the prices compare very favourably with those we have hitherto paid. Messrs. Keats are now carrying on a very large manufacture, which, by an extensive system of machinery, is complete in all its details. They now make every description of goods, from the heaviest clump sole to the child's shoe, as well as a great variety of pumps, or single sole boots. Their latest production is the "Eureka" boot, which aims at—and, we think, reaches—perfection in walking gear. The object is to render the walking boot practically waterproof, and to do away with the uncomfortable inertia to which the side elastic subjects the ankle joint. The front part of the boot folds back and forward again under the lap of the back part, which is continued forward and fastened with a buckle. This arrangement secures a fit round the ankle joint, and prevents the foot slipping forward in the boot by the yielding of the elastic.

In the "Crispin" process of manufacture the last is so constructed as to be variable, by the insertion of wedge-shaped middle pieces; thus a special last is not needed for every foot, although of course, there are various sized lasts. After selecting a suitable last, metal base patterns are prepared, from which the upper parts of the boot are cut. The uppers having been closed are adjusted to the insole and a welt is held to their outer edge, the whole being sewn together by the Crispin sewing machine, one seam taking only thirty seconds to complete. The welt is then turned over and adjusted to a sole, the two being sewn together in the same time as the previous operation. the four seams of a pair of welt boots thus taking two minutes to sew. This work, when done by hand, occupies about an hour and a-half. The feather is then formed in a few seconds, the result of this operation being to conform the upper to the contour of the outsole, and to make the insole perfectly smooth. The boot is then taken to the lasting machine, the last being inserted by mechanical pressure. This process insures a perfect fit, as the upper is not unduly strained in any one The heel is then sewn on by the Crispin machine, after which the boot is sent to a paring machine, where the edges of sole and heel are trimmed up. It is then ready for finishing off in the customary way. Thus, from first to last, we have boot making performed well and thoroughly by mechanical means. The manufacture is by no eans experimental; it is practical, and the machinery at Messrs. Keats' works is capable of turn-ing out several thousand pairs of boots per week. They have competed successfully with the makers of hand-sewn welt boots in contracts for the supply of boots to public bodies, and they have a large private trade at home and abroad. By a method of self-measurement, arranged upon the metric system, by Messrs. Keats, boots can be supplied to persons at any distance who can send their instructions by post. Of course, all this per-fection was only attained by a long and tedious process of development, in which Messrs. Greenwood and Batley, as machinists and co-inventors with Messrs. Keats, had no small share. The rewult of a combination of the inventive talent of the latter with the mechanical genius of the former gentlemen has resulted in the realization of a new a in the ancient art and mystery of boot-making, highly ereditable to the inventors, and beneficial to the public.

THE CAPTIVE BALLOON FREE.

GIFFARD'S magnificent balloon, which was fully described in our last impression, made escape from captivity last Tuesday afternoon. It had made an ascent with ballast only in the car. previously to taking up a company of aerial voyagers, as is the usual practice to make sure that all is safe. The wind, however, was very high, and carried the balloon over to a very sharp angle when near the ground. The grooved pulley, over which the rope passes, failing, somehow or other, to follow the angle of the rope sufficiently quick, the latter slipped off, and the strands became damaged on the edge of the pulley. Thus weakened, the ascensional power of the balloon, aided by a stiff breeze, soon severed the rope, and the balloon shot upwards. We are glad to learn that it has since been secured, near Aylesbury, although we regret that some slight damage has befallen it. Observations made in the neighbourhood of Aylesbury show that the balloon came from the direction of Aston Clinton and Tring, and passed a little to the north of the town of Aylesbury, going westward. It bore for the Waddesdon and Winchendon range of hills, and by Tring House, Hogshaw, and North Malston, past the Grandborough-road Station, on the Aylesbury and Buckingham line of railway, to a farm in the parish of Botolph Claydow. The balloon, after passing the Winchendon hills, showed signs of partial exhaustion, and for four or five miles the portion of rope attached to it dragged along the fields and against the hedges. It then proceeded on again, coming into contact with some large elm trees on Bernwood Farm, on the estate of Sir Verney, with which, after tearing away some large branches, it became entangled. It was eventually secured by the inhabitants, under the direction of Sir Henry Verney, and the manager's staff have since taken charge of the monster. No apprehension need be entertained as to the safety passengers if the balloon had broken loose during the ascent of a party, because, in that case, MM. Godard and Aymo would have been in the car, and would have landed the balloon and passengers in safety within a comparatively short distance of Ashburnham Park.

#### GUNPOWDER HAMMER AND PILE-DRIVER.

T a late meeting of the Franklin Institute A there was exhibited a gunpowder hammer, invented and constructed by Mr. Thomas Shaw, of Philadelphia, and to which implement we recently briefly referred. In describing the apparatus, Mr. Shaw said:—Among the first and most useful mechanical instruments is the hammer; but the muscular effort necessary to throw the ordinary hammer is too expensive to permit this mode of operation to be universal; hence other sources of power have been called into requisition, such as wind, water, and steam, and it is now proposed to add gunpowder to the list. In the introduction of gunpowder for operating hammers, several advantages over all other sources of power are secured In the employment of a concentrated fue combined with a sufficient supply of oxidizing materials to make its combustion independent of artificial or natural draught. 2. In the completeness with which the principle of expansion that can be brought into play, without cut-off valves or complications of machinery, and as it is only at high pressures that the value of expansion becomes prominent, we here have it to the fullest extent. 3. In the readiness with which the machine can be started. Its going into action being simultaneous with the ignition of the fuel, and the immediate cessation in use of fuel with the stoppage of the work. 4. In the simplicity of the machinery; for while the gunpowder hammer is the most powerful, it has not the tenth part of the complications of other hammering appliances. 5. In its controllability; for this most powerful of all operative forces can be regulated by a child. 6. In economy, for it is less expensive than other machines, because the fuel is employed to the best possible advantage, and because the heat is not radiated and lost from innumerable surfaces

The modus operandi of bringing about these results is as follows:—A weight or hammer is suspended between vertical guides, and is provided on ts under side with a plunger that fits into the bore of a cylinder held between the same guides beneath the hammer. It is intended that the cylinder should rest upon the object to be pounded, and

core connected with the same, whereupon the A small amount of hammer is allowed to fall. powder is placed in the cylinder; the hammer falling, forces its plunger into the cylinder, compressing and heating the air, which explodes the powder, forcing the hammer up again, and forcing the cylinder downward with an effect fully eight times as great as from the fall of the weight alone. At the top of the guide frame is suspended a plunger, which fits into a cylinder in the top of the hammer, thus making an air-chamber to receive the blow of the hammer in case of an over-charge of powder, that no danger may result to the ma-

chine. I will here mention that this device is very t ful as a drop-hammer, being complete within itself and always ready for work, independent of other source of power. Also, as a forge-hammer, the continued pressure of the blow gives this hammer evident advantage over all others for large work; for it will be observed, that the pressure is continual while the hammer is moved from a state of rest through a space equal to the length of the bore of the cylinder, which, in a large hammer, is a distance of 40in., whereas, in other methods of hammering, the pressure is lost as soon as the momentum is overcome, in spattering the surfaces of a large mass of metal. From this it results that large masses are never homogeneous to their centres, and the outer shell is put under a severe crushing strain, while the inner metal is under a like tensile strain, and thus a great loss of effective resistance occurs. Wrought metal should be kneaded and worked, as dough, to bring out its highest qualities. An hydraulic press would be the most suitable appliance, but for its slowness, which involves great loss of heat before the metal is fully manipulated. It is here that gunpowder comes to our aid, giving the continued pressure of the hydraulic press combined with the rapidity of the hammer, and thus renders possible the working of iron under the hammer like putty under the The advantages of thus pressing metal are too prominent to need enumerating.

The model which was exhibited on this occasion had a ram of about 3lb. weight, and a fall of 8ft. The charge employed was half a grain of white gunpowder, made of chlorate of potash, ferrocvanide of potassium, and sugar. With a white gunpowder, made of entorate of potassium, and sugar. With a larger instrument, whose ram weighed 73lb., with a fall of 20ft., the charge was 14 grains of the same powder. A pile placed under this, and driven one-quarter inch at a stroke by the fall of the ram, without the use of powder, was driven 2in. at each stroke, when the powder was used, and after being driven, with a square end, into hard ground, to a depth of 4ft., showed no splitting

or injury to its head.

# THE BRITISH ASSOCIATION.

THE thirty-ninth meeting of the British Association for the Advancement of Science, will commence in Exeter, on Wednesday, August 18 next, under the Presidency of George G. Stokes, M.A., D.C.L. Sec. R.S., Lucasian Professor of Mathematics in the University of Cambridge. As Exeter has never yet received a visit from the Association, the following information may be useful. The population of the city is about 42,000. The hotel and lodgings accommodation in the city is quite equal to that of the majority of towns visited by the Association. Exmouth, Dawlish, and Teignmouth watering places, within about half-an-hour's journey by railway, have ample accommodation for visitors and their families. Exeter is about five hours distant from London, by the Great Western and South-Western Railways, and is on the main line of railway to North and South Devon and Cornwall. Members proposing to make a tour through Devon and Cornwall should obtain tourist tickets, which will be supplied to any one member, on production of a card of membership, from all the principal stations in England. Tourist's tickets are available for a calendar month, and for a longer period, by a small further payment. The journey can be broken at Exeter, both in going and re-turning to North or South Devon and Cornwall. Members can obtain return tickets, available from August 16 to 28, on production of their card of membership, at ordinary return ticket fares. The Local Executive Committee have issued a map of the West of England, with the objects marked thereon, which are likely to be of interest to the members of the Association. Invitations have been already received by the Local Committee from inhabitants of Plymouth, Devonport, Torquay. that the hammer should be held by a pawl, which and Taunton, for the members of the Association catches into a rack secured parallel with the guides. The pawl is released from the rack by a it is expected that excursions will be made to

North Devon, Dartmoor, and other places of scientific interest, during the meeting. The head quarters of the Association are at present in the Albert Memorial Museum, Exeter, the honorary local secretaries being Messrs. Henry S. Ellis, John C. Bowring, and R. Kirkwan.

### DETERMINATIONS OF FREE OXYGEN.

T a meeting of the Manchester Literary and A Philosophical Society, Mr. Peter Hart de-scribed his method of making rapid determinations of free oxygen. The apparatus required consists, in addition to an ordinary pneumatic trough, of two tubes, each ½in. diameter and 16in. long, closed at one end. One of the tubes is graduated into 50ths of a cubic inch, and the other is coated internally with phosphorus. This is effected by dropping into the tube a few pieces of phosphorus; it is then to be closed by a sound cork, and the phosphorus (melted by immersing the tube in hot water) may be spread in a thin coating over the interior by turning it round as it cools. On cooling, the cork is to be withdrawn, the tube filled with water, and a piece of india-rubber tube tied securely over the This completes the apparatus. The modus mouth. operandi is as follows :- Both tubes are filled with water and allowed to remain in the trough, a por-tion of the air to be examined is passed into the measuring tube, which is now allowed to remain for five minutes in the trough to allow it to attain the same temperature as the water. It is lifted until the water is at the same level within and without, and may then be closed by the finger, and withdrawn from the trough. The volume is easily noted. This done, it is connected by the india-rubber joint with the phosphorus tube, into which the air is allowed to flow. The whole may which the air is allowed to flow. The whole may now be placed for half an hour in the trough, when the gas may be poured back into the measuring tube, the level once more taken, and the volume read off in the same way as before. The loss is oxygen. In the cut, a is the measuring tube, b the india-rubber junction, and c the phosphorus tube.

# 

No claim is made for strict scientific accuracy in connection with this apparatus; its sole merit consists in its offering an easy and rapid means of approximately determining the free oxygen in an atmosphere. In the working of sulphuric acid chambers it has been found extremely valuable, and possibly may be found so for other technical inquiries.

THE STREET TUNNEL AT CHICAGO AND ITS MACHINERY.\*

By PROF. S. W. ROBINSON, C.E.

T the time of my visit to the Chicago Washington-street Tunnel, on the 13th inst., the work of tunnelling under the river was considerably more than half completed. The approach and arched way on one side are entirely finished as far as to the centre of the river, and work has begun briskly on the opposite bank. The bed of the river consists of soft, tough clay. It is, therefore, impracticable, if not impossible, to drive the tunnel without unroofing it, especially under the river's bed. And as it is necessary to continue the work without interrupting the river navigation, and still uncover the roof, it became necessary to establish a coffer-dam that should extend to only about half of the river's breadth at one time. By means of such a dam, the tunnel has been completed up to the centre of the river, and covered again. dam was then transferred to the opposite shore, shifting at the same time the passage for boats.

The second dam was completed on the 13th inst.,

and the water partly withdrawn with the pumps still working. Two pumps were in operation—a rotary and a vacuum pump. The latter is of new design, and deserves more particular mention. It will directly be more fully described. The work of uncovering the tunnel bed has begun on this side, just beyond the dam or river bank, and proceeded to a depth of 50ft, with about the same length and breadth. When the coffer-dam emptied, the excavation will be extended into it, and the finished part of the arching brought for-ward beyond the limits of the river and covered. The dam then can be removed from the river entirely, and the tunnel continued to its second approach.

Two power derricks are in use for hoisting and

shifting the excavated material, only a part of which is required to be taken away, viz., a volume equal to that of the tunnel, the approaches, and the masenry. The balance is to be transferred from its native bed to the top of the tunnel. In doing this, the derricks command about a cubic vard at a lift, which is raised at the rate of a foot per second, taking and depositing it at about 15ft. from the centre mast. The clay is so soft, that the sides of the excavation must be supported to protect the foundations of adjacent buildings. This is effected by means of cross timbers pressing against plank walls. The clay is handled with hay forks, it being previously cut into lumps with sharp spades. It was noticeable that the workmen were very careful to entirely free every lump, that it should not be found tied down by the tenacity of a small unsevered fragment. On the whole, the work appeared to be progressing very favourably, with a good prospect of a speedy and successful termination

The vacuum pump spoken of above, is simple, and, it is said, very efficient. It consists of a cylindrical chamber of wood, strongly hooped, being about 3 ft. in diameter, and about 5ft. in height; having suction and discharge pipes with valves properly arranged, and a steam pipe leading from a boiler; together with a small injector vessel supplied with water. Steam of the desired pressure is forced into the chamber by the steam pipe, when the admission is arrested by a three-way valve; a branch pipe leading therefrom, terminated by a check valve, allows the escape of steam from the chamber until the pressure of the atmosphere is reached. As soon as this occurs, a valve drops in the vessel upon the top of the chamber, introducing a spray jet, by which the remaining stream is condensed, thus forming the vacuum. The valve of the suction pipe is then raised, and water rushes in from below and fills the chamber. This done, steam is again forced into the same chamber in contact with the water, which promptly retires before it through the discharge pipe. The small injector vessel is filled with water from the dis-charge pipe. When the water is driven out, the three-way valve checks the steam, and the vacuum is again formed, and the above described opera-tions repeated, which may be so continued indefi-nitely. The three-way valve was operated by a person stationed for that purpose. The water was raised about 12ft., to be discharged over the dam. By a similar machine, it is said, water has been raised in a jet to a height of over 100ft.

A question is naturally raised as to whether this is an economical method of using steam. Let us consider this subject briefly. It was ascertained by actual observation with thermometers, that the water discharged over the dam by this pump, was increased in temperature two degrees. By calculation, it is determined that the condensation of the steam remaining in the chamber at atmospheric pressure, is sufficient to raise the temperature of the chamber full of water about two-thirds of a degree. There is then imparted one and one-third degree of heat to the water, by reason of the admission of steam to contact with it, and with the wet interior surface of the chamber. The prejudicial result effected by operating this contrivance is then represented by the mechanical effect equivalent to heating all the water discharged one and one-third degree. It was determined by Joule and Mayer, independently, that to raise the temperature of one pound of water one degree, requires a mechanical effect equal to raising 772lb. 1ft. The volume discharged per minute, at the rate of three strokes, is 144.3 cubic feet, or 9018.71b. To raise this 12ft. per minute, requires three and three-tenths horse power. But to heat it one and one-third degree, requires perminute a mechanical effect equal to 9018.7 × 772 × 1 = 9280244 ft. pounds = 281-horse power. But the steam was all taken from a 15 or 20-horse boiler. What, then, is the mechanical equivalent in this case?

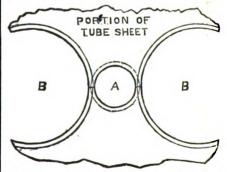

But let us take another view of the case. heat a given quantity of water one and one-third degree, takes twice as much steam as to heat it two-thirds of a degree. Then if 144.3 cubic feet of steam, at atmospheric pressure, will heat the same volume of water, at the ordinary temperature, two-thirds of a degree, twice the quantity of steam at atmospheric pressure will raise the temperature of 144.3 cubic feet of water one and onethird degree. If the last named quantity of steam, which is the amount lost by incidental condensation, be used each minute in a steam cylinder at 60lb. apparent pressure, it would perform the work of two and a-half horses. Taking this as the prejudicial work of the vacuum pump, and 3.3-horse power, which was shown above to be the theoretical work required to raise the water, we find that

the work lost is 0.76 of the useful effect; and 0.43 of the total effect; which is a large per centage for even ordinary pumps. If this is true, it appears from the results of the experiments cited, that as a device for raising water, the vacuum pump is not an economical machine, except where con-venience demands its use, or where its temporary employment justifies the application in preference to more costly machinery.

One of the most essential pre-requisites for economical results with this device, is, that the surfaces with which the steam and water have alternate contact, must be non-conductors of heat. Indeed, the measure of success depends upon the degree to which this principle attains. at first naturally suppose that the cold water surface would contribute to rapid condensation of steam. But it is very well known in the science of physics, that water is one of the poorest conductors of heat; which becomes particularly apparent in the downward direction where conviction fails to act. A remarkable statement, substantiating this fact, on a large scale, appeared in the "Scientific American," early last spring, in which it was confidently asserted that one of two boilers of moderate size, established in separate arches, connected by a steam pipe, having no separating valve, had frequently been fired while the other was not, although still containing the ordinary supply of water; and that the water in the unfired boiler had not changed materially in temperature after a considerable interval of time. From this, together with the facts relating to the vacuum pump, it appears that water is a poorer conductor of heat than the wet wood of the interior of the chamber, as the amount of condensation incident upon the ejection of water is very considerable. If so poor a conductor as wood is barely suitable for the interior of the chamber, iron could not possibly answer, notwithstanding the want of its strength to guard against explosion; although iron cylinders lined with wood or other non-conducting material, might serve the purpose well, some good non-con-ducting material having little inclination to retain water, as wet would form the best lining. That so good a conductor as iron cannot form the interior surface, is strikingly shown by the performance of certain surface condensers. In Hamilton, Ontario, at the machine works of the Northey Brothers, a 12-horse engine exhausts into a cylindrical wrought-iron chamber, about 2½ft. in diameter, and 30ft. high. It is of boiler plate, about 5-16ths of an inch thick. A stream of water delivered upon the top flows down over the whole exterior surface. chamber maintains nearly a perfect vacuum.

### THE TUBE SHEET.

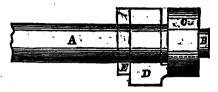

THERE is nothing, perhaps, among the duties of the steam engineer which occasions more anxiety often than leakages among the tubes in the fireplace of the boiler, especially in the locomotive boiler, caused, perhaps, by heedless firing or not unfrequently by the unskilful setting of the tubes in the first instance. The setting of tubes should never be entrusted to any but thorough and trusty workmen. The tube sheet is often strained if not cracked by the immederate driving of the "tube range" around which the tube is unset, and by too plug," around which the tube is upset, and by too hard upsetting of the end of the tube. The plug should never be driven hard enough to expand the tube hard up against the hole. It is better to do this by upsetting the tube, thus making the tube thicker and stronger at its point of juncture with the sheet. In annealing the ends of the tubes, in preparing them for setting, care should be taken not to heat them more than an inch or so, just sufficient for the upset. A light hammer should be used with the setting tool, for it is better to mass summent for the upset. A light hammer should be used with the setting tool, for it is better to pass several times around the "tube plug" with light blows, than to attempt to accomplish the same end with a few heavy blows, which may strain, and perhaps crack, the sheet between the tubes—espe-

cially when the tubes are as near together as in locomotive boilers. When the sheet cracks between locomotive boilers.

<sup>\*</sup> Journal of the Franklin Institute, January, 1869.

two adjacent tubes, it may be repaired by screwing in a fine threaded plug A, nearly large enough to fill the space between the tube holes, B. (See diagram, which represents a section of a tube sheet.) Before screwing in the plug A, the hole must be counterbored sufficient to cut into the counter-boring of the tube holes B, as shown by the dotted circle; then the plug A may be headed down with a light hammer, so as to make a steam-tight juncture with the end of the tube. The outside circle around the tube holes B shows the amount of counter-boring. The plug A must be slightly tapering, and screwed in firmly. A convenient tool for counter-boring tube holes is represented in the following diagram. tube holes is represented in the following diagram.

A the arbour, which may be made of steel about 6in. long exclusive of the shark; B the tit upon which the ring C is fitted; this ring is for a guide to fill the tube hole; D the cutter; E the wedge. There may be as many rings C as there are sizes of tube holes. The nib of the cutter must be set to agree with the ring, as shown.—"F. G. W.," in the "American Railway Times."

#### ELECTRIC FIRE SIGNALS.

PRACTICAL illustration of the value of the A PRACTICAL illustration of the value of the electric system of signalling in houses is given in the recent fire at the seat of the Duke of Northumberland, at Albury Park. There the first alarm of the fire was given by means of the electric bells and fire alarms with which the mansion has been fitted, by Mr. Sax, of No. 108, Great Russell-street, Bloomsbury, and who has patented the system. This is, we believe, the first instance in which the application the first instance in which the application of electricity, as a self-acting fire alarm, has been practically illustrated. Had it not been for this timely warning, the consequences of the fire might have been far worse than they were. We can bear testimony to the value of these signals, can bear testimony to the value of these signals, although not, we are happy to say, from actual conflagration, although, nevertheless, from fire. Our office was fitted some two years since with Mr. Sax's electric bell as a means of communication with another department. The signalling button was placed beside the fireplace, and being set very fine, a little extra firing one day started the bell, and brought our office boy up with a run. This is ample testimony of its efficiency under temperatures higher than ordinary.

## THE ARTIFICIAL PRODUCTION OF ICE AND COLD.

### BY DR. B. H. PAUL

THE application of heat for cooking food has been THE application of heat for cooking food has been considered one of the most obvious characteristics by which man is distinguished from the lower animals, and there is even still greater reason for regarding the application of this physical agency for various economic and industrial purposes, as being one of the circumstances most important in determining the difference between civilized man and savages, and most conducive in various ways to the spread of civilization.

ing the difference between civilized man and savages, and most conducive in various ways to the spread of civilization.

In most of the industrial arts, the application of heat is involved in some one or other of the operations to be performed. Through the medium of vapourized water, it is the principal means of locomotion on land and by sea, as well as the chief source of motive power; while in the extraction and working of metals, and in most productive arts, involving chemical alteration of raw materials, it is essential for bringing about the various changes to be effected. But, though chemical alteration is, in many cases, the object to be obtained in manufacturing operations, and then the application of heat is the means by which that change is facilitated, there are some cases in which it is desirable to hinder or prevent the chemical changes to which certain materials are liable even within the ordinary range of atmospheric temperatures. Thus, for instance, all articles of food, and especially those of animal origin, when kept for any length of time at the ordinary temperature, undergo a chemical change which renders them unfit for use. They pass into a state ofputrefaction or decay, and are gradually resolved, under the influence of atmospheric exygen, into the simplest forms of combination their elements are capable of assuming. For this change, a certain temperature is essential, and though it probably, cannot capable of assuming. For this change, a certain temperature is essential, and though it probably cannot

be prevented altogether, it is very considerably hindered by a reduction of temperature. Thus, for instance, in Siberia, the carcases of mammoths have instance, in Siberia, the carcases of mammoths have been found in a very perfect state of preservation, notwithstanding the vast lapse of time they have been buried in the frozen soil. In like manner, meat, and game, or fish, may be preserved for a long time, quite fresh, by keeping it at or below the temperature of freezing water. For this and other purposes which require a low temperature, and where it is desirable to abstract heat, instead of applying it to any substance, ice has been largely employed, and the importation of ice into this country from higher latitudes has become a very large trade since the vear 1840 year 1840.

year 1840.

Ice acts as a cooling agent in virtue of the physical fact, that, in common with all solid substances, it requires an expenditure of heat for its conversion into the liquid state. The heat thus applied does not fact, that, in common with all solid substances, it requires an expenditure of heat for its conversion into the liquid state. The heat thus applied does not produce any elevation of temperature, but as the ice melts it disappears, so far as the indications of the thermometer will show, and there remains a quantity of water of the same temperature as the ice itself. Thus when ice or, still better, snow, is mixed with three-fourths its weight of boiling water, the water remaining after the ice has melted, has a temperature of 32deg. Fah., the same as the ice itself; the quantity of heat in the boiling water, corresponding to the interval of temperature between 32deg. and 212deg. Fah., having been rendered latent, or expanded in effecting the liquefaction of the ice. It is in this way that ice cools water, air, or any other substance it is brought in contact with, which has a temperature higher than 32deg. Fah. Hence it will be seen that refrigeration, or the production of cold, is simply a manipulation of heat. It is an operation in this respect perfectly analogous to the production of a high temperature, in so far as both processes consist in the transfer of heat from one substance to another, and are subject to the same general laws. They are, however, reverse processes. Thus in generating steam, heat produced by the combustion of fuel is communicated to water. In making ice, on the contrary, heat is abstracted from water, and in this process, the water which is cooled corresponds to the fuel burnt in generating steam, or in converting any other substance into vapour. Just in the same way that the fuel in burning yields its heat to the substance vapourized, so does the water, in making ice, yield its heat to some other substance capable of receiving it. This is the nature of the work to be done in making ice, and it is now necessary to consider the amount of that work requiste for producing a given quantity of ice.

Water at the temperature of 60deg. Fah. contains an amount of heat greater than that contained i

Heat units. lbs.  $882,256 = 2,240 \times 170.65$ .

882,256 = 2,240 × 170.65.

This is a quantity of heat not more than about one-eightieth part of that capable of being generated by the combustion of a ton of ordinary coal. The means by which this amount of heat may be abstracted from water consist in producing some physical change involving an expenditure of heat, and doing this in such a way that the heat required for and applied to that purpose, is abstracted from the water to be cooled and frozen. The conversion of any substance into vapour is a change of this kind, which involves an expenditure of heat similar to that taking place in the melting of ice. The amounts of heat thus absorbed by various substances in vapourizing are as follows: are as follows :-

Latent heat per lb. Authority. Regnault.
Favre and Silbermann . . . 364.3 .} Andrews. Ether .

The amount of heat thus disposed of and rendered latent in the formation of steam from water is considerably greater than that existing in the latent condition in liquid water, or, what amounts to the same thing, that expended in melting ice; but the vapourization of water cannot be applied as a means of refrigeration to any great extent, because under the ordinary atmospheric pressure it does not take place readily, or with sufficient rapidity at temperatures much below the normal boiling point, or 212deg. Fah., and even when the pressure is removed by means of an air pump, the vapourization of water proceeds very slowly at low temperatures. There are, however, other substance which vapourize readily under these conditions; and, for this reason, although the amounts of heat expended and rendered latent in their vapourization are less than in the case of water. Ether, alcohol, and liquid ammonia are substances of this kind; and, according to the fore-The amount of heat thus disposed of and rendered

going data, expressing the latent heat of their vapours, the quantities of each of these substances which going data, expressing the fatent neator their vapours, the quantities of each of these substances which would have to be vapourized, in order to produce a ton of ice from water at 60deg. Fah., or to produce a refrigeration equivalent to the melting of a ton of ice, would be:—

From this comparison, it will be seen that the expenditure of heat accompanying the vapourization of liquid ammonia is much greater than it is in the case of alcohol or ether, and that in this respect it is the most powerful as a refrigerating agent. But the amount of heat rendered latent in the vapourization of any motorous is not the old rendered head. amount of heat rendered latent in the vapourization of any substance, is not the only or even the chief point which determines its efficiency of a refrigerating agent. The degree of facility with which a substance vapourizes at low temperatures is of still greater importance, as will be evident from the following table, which gives the tension of the vapours at different temperatures below the boiling points of the liquids under normal atmospheric pressure: ressure :-

Normal Boiling Point.	Ammonia.	Ether.	AlcohoL	Water.
Notate Boning Foric	28deg.	95deg.	172deg.	212deg. F.
deg. Fah. 104 63 50 pour in inches of mercury at -4 -109	inches. 463-64 254-61 181-58 124-52 55-03 20 81 9-45	inches. 35:81 17:06 11:28 7:23 2:66	inches. 5-26 1-75 -96 -50 -13	inches. 2·16 -68 -36. -18

Since the tension of a vapour at any temperature is the measure of the facility with which the liquid is the measure of the facility with which the liquid evaporates at that temperature, it will be seen from the data in this table, that, in this respect, there is a very considerable difference between the liquids there named. Here, again, the characters of liquid ammonia are such as to give it a marked precedence over all the other liquids, as a refrigerating agent, by reason of its relative capability of vapourizing at very low temperatures. This substance is, in fact, gaseous under normal pressure, within the ordinary range of atmospheric temperature, the boiling of the liquid being many degrees below the zero of Fahren-eit's scale: and at ordinary temperatures it requires heit's scale; and at ordinary temperatures, it requires a pressure of from eight to ten atmospheres—117 to 150lb. per square inch—to maintain it in the liquid

Alcohol, although it has a greater capability than ether of absorbing heat in vapourizing, is still inferior to ether as a refrigerating agent, on account inferior to ether as a refrigerating agent, on account of its being much less readily vapourized at low temperatures; and even ether evaporates so slowly at temperatures much below its normal boiling point, that it can be used for refrigerating only with the aid of an air pump to maintain the requisite rate of vapourization. Liquid ammonia is, therefore, by far the most efficient material to use for this purpose, not only on account of its ready vapourization at low temperatures, but also, because its power of absorbing heat in that change is but little inferior to that of water.

ing heat in that change is but httle interior to that or water.

Another process, in which heat is expended and rendered latent, is the expansion of air. The amount of heat thus absorbed is at the rate of -069, or about 1-14th of a heat unit for each pound of air expanded to the extent of -002035, or about 1-490th of its volume at 32deg. Fah. under normal pressure. If, therefore, air be compressed, say, to one-tenth of its bulk, and, after being cooled to a low temperature, it be allowed to expand in such a way as to perform mechanical work, such as moving a piston, there is an expenditure of heat proportional to the resistance overcome and to the degree of expansion. Consequently, the temperature of the gas is reduced during the act of expansion, and this effect may be taken advantage of for purposes of refrigeration. The chief disadvantage of this method consists in the great expenditure of power requisite for compressing the air, which involves a large consumption of fuel.

(To be continued.)

### RANGE EXPERIMENTS FOR FIELD ARTIL-LERY AT SHOEBURYNESS.

LERY AT SHOEBURYNESS.

SOME time since, we ("Standard") recorded the first trial of an interesting system for ascertaining the distances of objects in the field by instrumental means, devised by Lieutenant Nolan, R.A., as against the ordinary system in the service, of judging the distances by eye alone. Since then, other instrumental means have been proposed by other officers and by opticians; and on Wednesday week a competitive trial between several of such instruments, designed to ascertain rapidly distances for artillery purposes, was made at Shoeburyness, under the direction and in the presence of the Commandant Colonel Elwin, R.A. Four telemeters, constructed upon different principles, were employed. The first, made by Mr. Elliot, is a telescope containing micrometer cross wires; one of these is

<sup>\*</sup> Reproduced by permission of the publishers from the Quarterly Journal of Science."

<sup>\*</sup>The unit of heat here referred to is the quantity of heat required to raise the temperature of a pound of water from 40deg, to 41deg, Fah. or one degree of tem-

fixed, the other movable. The man whose distance is desired being brought within the field of the telescope, the fixed wire is seen in line with his feet, telescope, the fixed wire is seen in line with his feet, and the movable wire is made to appear to touch his head: this latter movement is effected by a ring round the small end of the telescope, which is graduated in yards, so that as soon as the wires are properly adjusted the range may be read off at once. Another scale gives the distance of a horseman. The second system is that of Colonel Clerk, R.A. It may be said to consist of two very powerful and much simplified sextants, which are worked at each end of a base of 100 yards. The mean of the angles which they give being ascertained, a table shows the distance.

which they give being ascertained, a table shows the distance.

The third instrument has been invented by Mr. Adie, and has already been used by surveyors and sportsmen. A metal case, one yard long, contains two telescopes, of which the object glasses are at the extremities, and their common eye-piece in the centre; two pairs of prisms bend the rays of light, so that from the two ends they reach this common eye-piece, which has one of its glasses cut in halves. When the two telescopes have been made by a small handle to converge on any object, a single image is seen in the eye-piece; when they do not so converge a double image is discerned. A scale divided very finely to two seconds shows how much the handle has moved the interior of one of the telescopes; and finely to two seconds shows how much the handle has moved the interior of one of the telescopes; and corresponding to the small angles read off on this scale are the distances shown on an ivory tablet affixed to the instrument. Lieutenant Nolan employs two guns, on which are affixed cross telescopes; the distance between the guns was for the first five cases 57, and for the remainder 93 yards. By a system of mechanical calculation, or modification of sliding rule, he combines the base and base angles so as to give the range.

To test these various instruments a mounted sergeant was sent along one of the lines of pegs which mark the distances from the several batteries at Shoeburyness, and whenever he halted his dis-

which mark the distances from the several batteries at Shoeburyness, and whenever he halted his distance was estimated by the different systems, the answers being given to Captain Alderson, R.A., Assistant Superintendent of Experiments, and afterwards compared with the true position of the sergeant. Mr. Adie manipulated his own telemeter, Lieut. Ellis, R.A., that Mr. Elliot; Mr. Butters, of the Royal Carriage Department, Woolwich, Colonel Clerk's; and a party of gunners, under the superintendence of Lieutenant Nolan, that of the latter gentleman. The results are given below:—

True Distance.	Errors.

# Acgal Intelligence.

COURT OF CHANCERY. May 25.

(Before the LORD CHANCELLOR.

IN RE BATES AND REDGRAVE'S PATENT.

was a question with respect to a patent which had been filed under a provisional specifica-tion. It seemed that a second inventor had since lodged a provisional specification for the same subject matter, and had procured its being first sealed. It was submitted by the petitioner that the filing of the provisional specification in this case ought

to have secured the rejection of the second patent.
Mr. T. Webster, Q.C., Mr. Grove, Q.C., Mr. Everitt,
and Mr. Aston appeared.
The Lord Chancellor said that with regard to
the interpretation of the statute, which provided
the machinery of provisional specifications, he was
of opinion that an inventor who had filed a provisional specification after another person had filed
one on the same subject, but who had contrived to
have his patent first scaled, was in the same section have his patent first sealed, was in the same position as he would have been before the passing of the Act.

The benefit conferred by the statute on inventors from a provisional specification, was protection against the consequence of imprudence on their

own part, or of a betrayal of confidence on the part of their working or others. Now, complete protection might have been obtained by filing a complete specification, under section 9, but that had not been done by the petitioner. An inventor who had filed a provisional specification could not be compelled to proceed with his invention, and, therefore, if the Atternet Characteristics of the compelled to proceed with his invention, and, therefore, if the Attorney-General rejected a second applica tion, in consequence of a provisional specification having been already filed, the public might be deprived for years of the benefits resulting from the ingenuity of many minds working together in the same direction. The petitioner could not be protected from the consequences of his own omission. Under the circumstances, however, the Court would not give costs.

#### TO CORRESPONDENTS

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in

advance.
All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANIC, "MAGAZINE Office, 166, Fleet-street, London.
To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday exeming.

ments should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Advertisements are inserted in the MECHANIOS' MAGAZINE, at the rate of 6d, per line, or 5d, per line for 18 insertions, or 4d, per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

# Correspondence.

APPLICATION OF LIQUID FUEL TO METALLURGY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,-My attention has been called to a leading SIR,—My attention has been called to a leading article in the issue of your valuable periodical for the 14th instant, on the "Application of Liquid Fuel to Metallurgy." I concur most fully in all that is there stated, respecting the benefits derived from the use of this fuel for metallurgic and steam purposes, and its great superiority over coal. In addition to a vast economy of time, labour, space, and first cost of material, as well as a superior article of manufacture, as rightly claimed in the above article, there are still other uses and purposes to which it is about to be as rightly claimed in the above article, there are suit other uses and purposes to which it is about to be applied, not inferior in importance to the foregoing. Seven years' continuous experience in the different methods of using liquid fuel, in the United States, in methods of using liquid fuel, in the United States, in search after the best means of utilizing the same, enable me to speak with considerable confidence on the subject. Having regard to the truth of what may become history, and while bearing the strongest testimony to the general correctness of the article alluded to, I am, nevertheless, compelled to take exception, when you add at its close, that "it was he (Mr. Dorsett) who first demonstrated the practicability of running a vessel of 500 tons burthen, by means of liquid fuel, and it was he who has now succeeded in advancing the science of metallurgy, &c."

Both these assertions are quite incorrect, as I will now prove to you. Locomotives were run by me upon a railroad in the United States, in 1863, and are to-day working there upon liquid fuel alone. For four years past, numerous oil wells in Pennsylvania have been pumped by steam power produced by my

system of liquid fuel. In the spring and summer of 1868, the "Island City," a Olyde-built side-wheel steamer of some 800 tons was in use in Boston Harbour, working on this new fuel; and you may remember the fact, that the importance or novelty of the event induced the President of the United States, while on a visit to that city, to make an excursion trip in her, down the Bay, in order to witness the working of this new steamfuel, of which he expressed a very high appreciation. Respecting its application to metallurgy, as early as the fall and winter of 1867, I was engaged in the city of New York in manufacfacturing wrought-iron blooms, weighing from 100 to 300lb., for boiler plate. This is surely a more severe test than merely heating those plates for bending. These solid blooms were quickly brought to a welding heat, and then worked under a 10-ton steam hammer, entirely by the agency of liquid fuel. I had previously patented and now use a new form of furnace and firebox, equally adapted to liquid and solid fuels. These systems are at the present time in operation in France, making steel and malleable iron, samples of which are now before me.

It is not my purpose at this time to advocate this or condemn that method of utilizing liquid fuel. I may be permitted, however, to remark, that during the many years I have been occupied with this subject, I have designed and secured patents upon several contrivances for the above purpose; at the same time, have tested and exploded many others, some for burning the liquid direct—others, first vapourizing then using it in jets, as practised by Mr. Dorsett. I now hold a patent for this system, granted in the United States, in the year 1863, reported in England and France some three years later, with slight modifications. In the first-named country, this vapourizing method of burning liquid fuel has been subjected to a most exhaustive trial, but, in the long run, it proved an entire failure. Besides, it is found quite dangerous, inasmuch, as by this process, there must be

267, Rue St. Honore, Paris, May 20.

[We are obliged to our correspondent for calling our attention to an omission in our article—that of the words "in England," after giving Mr. Dorsett credit for what he has done. We were aware that liquid fuel had been tried in more than one instance on large vessels in the States, but on a different principle. Our correspondent's remarks upon the result of the application of liquid fuel to the manufacture of boiler plates are a practical comment upon our observation, that we may "expect further and even more important improvements in the application of the system." With regard to the burning of the fuel either directly as an oil, or indirectly as a vapour, we, like our correspondent, do not propose here to discuss the relative merits of the two principles. They are well known. We would only observe that the Dorsett process has accomplished in England what no other process has. Whether other systems could give such results, is open to proof by their respective inventors.—Ed. M. M.]

# THE SMOKE NUISANCE.

"The Smoke Nuisance and its Remedy," you ask, "What about the noxious gases from the sewer, Mr. Richardson." Permit me in reply to say that my soot and water flue is provided with a drain eye entrance to the sewer, similar to common drains. The flap or door of the drain eye and younge to allow a flush of water. the sewer, similar to common drains. The flap or door of the drain eye only opens to allow a flush of water and soot to pass through and then closes; any ascent of odour from the sewer is, therefore, impossible. But supposing it was possible, would not the soot and water neutralize any rising odour? I consider the passing the soot of London into the sewers would not only deodorise them, but it would render the sewage of greater value as manure, and render unnecessary the troublesome process proposed of mixing it with common dry earth previous to its removal for use. The passage of a great quantity of water through the sewer might oblige us to provide outlets for its escape, but this could easily be done, and the water filtered through charcoal before it flowed away.—I am, Sir, yours, &c.,

FIFTEEN steamer gunboats are now being built for the Spanish Government in the Mystic navy yards of Connecticut. The gunboats are to be each 107ft. long, and measure 140 tons. Five navy yards, each employing 100 men, will be required to complete the contract. The machinery will be constructed in New York City. structed in New York City.

INTELLIGENCE is received from San Francisco of INTELLIGENCE IS received from San Francisco of the inauguration of the overland trade with China and Japan on the 9th inst. At that time the first invoice of tea from China to St. Louis was shipped by the Pacific road. The overland mails have been delivered at Promontory Point to the Central Pacific road, and the through line has been regularly established. blished.

According to the "Bureau Veritas" of Paris the ACCORDING to the "Bureau Veritas" of Paris the number of vessels reported as totally lost during the month of April last was 165, of which 71 were British. 27 American, 16 French, 11 North German, 5 Spanish, 5 Dutch, 5 Norwegian, and 25 of various other nationalities. This report contrasts favourably with those of the corresponding month of the three previous years, in which the losses were 189 in 1866, 265 in 1867, and 202 in 1868.

THE Board of Trade have awarded a binocular glass to Captain Mignot, of the French vessel "Arabie," of Nantes, for having rescued, on January 31, in long. 11-54 W. and lat. 47-39 N., Annana Howzy or Hoaze, one of the crew of the ship "Windsor Castle," of Liverpood, which vessel is supposed to have foundered at sea. The Board have greated for each to the four property. have also awarded £2 each to the four men who manued the "Arabie's" boat, and were instrumental in rescuing Hoaze.

Two 100-pounder steel muzzle-loading guns and two foo-pounder steel muzzie-toading guns and two 6-pounder breech-loading steel guns, manufac-tured by Messrs. J. Vavasseur and Co., of the Lon-don Ordnance Works, Southwark, were success-fully proved yesterday week at the proof butt, Royal Arsenal, Woolwich, with the ordinary proof charges, Major-Gen. C. H. Burnaby, Royal Artillery, being present on the part of the firm. These guns are intended to form part of the armament which will be supplied to the Japanese corvette "Iho-Iho-Maree," now building at Abordon. now building at Aberdeen.

A MOST gratifying circumstance connected with the Marine Society's training ship "Warspite" occurred during the Whitsuntide holidays. Ninetysix boys were granted leave of absence from Saturday last until the following Tuesday at four p.m., and at the prescribed hour the whole party, with one exception, returned to their ship at Woolwich. The system of training which could ensure such a result must be good; and these lads, when they eventually join the Royal Navy or merchant service, will not easily lose the habits of order and discipline learnt on board the "Warspite."

WE have to announce the death of Admiral Francis Decimus Hastings, who expired at his residence, Barbourne, near Worcester, on the 21st inst., dence, Barbourne, near Worcester, on the 21st inst., after a comparatively short illness. Admiral Hastings, who was a son of the late Rev. Jas. Hastings, rector of Martley, entered the service at an early age. He was commander of H.M.S. "Edinburgh" during the Syrian war in 1844, where he behaved with great gallantry. He was wounded by the bursting of a shell during the memorable attack upon and capture of Acre by the British squadron in 1840. For several years the deceased gentleman had been on the retired list.

GENERAL TODLEBEN, says the "Wiest," of St. Petersburg, has prepared a plan for converting Kieff into a strong fortress capable of holding from 50,000 to 60,000 men. This plan has been approved by the Government, and steps are now being taken for carrying it out. The General states in his report that the fortifications of that town are at present so weak that a hostile corps from Galicia or the Black Sea could penetrate without difficulty into the heart of the empire before a sufficient army could be placed so as to prevent its further progress. He therefore considers it absolutely necessary to make so important a strategical point as Kieff a strong garrison fortress.

CAPTAIN DAVID ROBERTSON, R.N., the Assistant Inspector of Lifeboats to the National Lifeboat In-Inspector of Lifeboats to the National Lifeboat In-stitution, has during the past two months been engaged inspecting the twenty-eight lifeboats of the Society on the Irish coast. Without a single excep-tion, he found the boats in admirable order, the crews tion, he found the boats in admirable order, the crews expressing the utmost confidence in them, and the local committees manifesting everywhere considerable zeal in the management of the lifeboat stations. It may be stated that the Institution has expended upwards of £15,000 on these twenty-eight lifeboat establishments, and that the support of the Irish boats involves an annual expenditure of about £1,400, which is partly met by the parent Society in London, and partly by local subscriptions.

and lengthened examination at the hands of Sir and lengthened examination at the hands of Sir Thomas Maclear and Mr. Tracy, the sailing master of the "Racoon." Their report is most favourable, and Mr. Davies is on his way to submit his invon-tion to competent authorities in England. He is backed by a recommendation from his Excellency Sir P. Wodchouse, who has taken a warm interest in the matter.

THE most destructive steamboat fire that ever occurred in Cincinnati, raged on the morning of May 12 at the landings of the New Orleans and Memphis packet companies. The fire broke out in the steamer "Clifton," and extended to the "Westmoreland," "Melnotte," and "Mary Erwin" above and to the "Cheyenne" and "Darling" below. and to the "Cheyenne" and "Darling" below.
The six boats were soon enveloped in flames. The
hulls of the "Melnotte" and "Darling" may be
used again; the others are a total loss. The fire
originated in the chambermaid's room on the "Cliforiginated in the chambermand s room on the "Churteen ton" by the upsetting of a coal oil lamp. Fourteen kegs of gunpowder on the "Cheyenne" exploded ane scattered the flames to the "Westmoreland." There were 200 barrels of coal oil on the "Cheyenne" and 25 barrels on the "Westmoreland." The loss and 25 barrels on the Westmore and. The loss of eight was 100,000 dols., which is nearly all insured The total loss is 235,000 dols.

# Miscellanea.

Gorn has been found in New Hampshire, but the report adds that the quartz when ground up is found to be a most valuable manure, and worth more for this purpose than the gold found in it.

A REQUEST has been presented by the ladios of St-Petersburgh to the authorities, soliciting permis-sion to found an establishment for the publication of literary works written by women.

It has been observed by several French botanists that all the large healthy trees of the woods of Ville d'Avray and St. Cloud are, in the immense majority of cases, thicker in the direction from east to west than in the contrary one.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending May 22, was 11,068. Total number since the opening of the Museum, free daily (May 12, 1858). 1,574,938.

A RETURN to an order of the House of Commons respecting the Bank of England was published on Tuesday morning. The parishes in which the Bank of England stands are St. Bartholomew, Exchange; St. Christopher-le Stocks; St. Margaret, Lothbury. The Bank and its premises are assessed to the poorrate at £37,540. The quantity of gold in its vaults on January 1, 1869, uncoined, was £8,760,397 7s. 5d.

THE cost of conveyance of the mails in the United Kingdom in the present year is estimated at £755,772 —£539,142 in England and Wales, £101,489 in Scotland, £115,141 in Ireland. The amount is rather less than it was last year, though the number of letters and papers carried is ever increasing. The payment onveyance of the mails by railway is estimated 412,592 in England and Wales, £80,499 in Scotland, £90.867 in Ireland.

An extra show of the Royal Horticultural Society. chiefly for pelargoniums, took place at South Kensington on Saturday last. The flowers staged were remarkably fine and well bloomed, and most of the remarkatory me and war broomed, and most of the prize specimens were magnificent. Amongst those who obtained the principal prizes for roses were Mr. Charles Turner, of Slough, and Messrs. Vaid and Co., of Cheshunt; for azaleas, Messrs. Veitch and Co.; and for orchidaceous plants, Mr. Williams, of Holloway.

THE number of visitors to the South Kensington Museum during the week ending May 22, 1869, (Whitsun Week) was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 28,811; Meyrick and other galleries, 6,127; on Wednesday, Thursday, and Friday (free) from 10 a.m. till 6 p.m., 4,517; Meyrick and other galleries, 1,413; total, 40,868. Average of corresponding week in former years, 21,709. Total from opening of Museum, 8465,204 years, 21, 8,465,204.

WA VOTE of £2.800 on account of the Wellington Monument is to be proposed to the House of Commons this Session. The original estimate for the monument was £14,000; £10,266 had been expended upon it up to the end of 1868, leaving £3,734 to be still voted. A vote will also be proposed of £667 towards the erection of a monument in Westminster Abbey to the memory of Lord Palmerston. The estimate for this monument is £2,000. £1,333 had been expended up to the end of 1868; the present vote, therefore, will complete the estimated amount.

MISS ALEXANDRE TINNE, the Dutch lady who WE last week referred to the circumstance that a gentleman at the Cape had invented an instrument explorer, has, according to letters received at Malta for ascertaining with accuracy the variations of the compass from local attraction or other causes, which are so puzzling and sometimes dangerous to navigators. The inventor is a Mr. J. H. Davis, of Colesberg, and his invention has undergone a most severe imported into Barbary a velocipede of the latest

Parisian manufacture; but finding it not adapted for the sands of the Great Desert, she presented it to the Pasha of Tripola.

A CONFERENCE of gentlemen interested in promoting the use of velocipedes was held on Tuesday afternoon, at the Inns of Court Hotel, Holborn. Mr. Alfred de Lavigerie was in the chair. The immediate object of the meeting was to consider the advisability of promoting the form ation of a velocity of the state of the chair of the cha nede and loco-machine institute. The objects of the pede and loco-machine institute. The objects of the institute would be to give prizes for the best velocipedes or carriages for public roads having any motive power except horses, and to in vestigate inventions or suggestions made in order to apply the velocipede to useful practical purposes.

The last of the race which died with him, Billy Lanny, known as "King Billy," the last of the aboriginal natives of Tasmania, has died at Hobart Town. For a long time, he has followed the life of a whaler, and was very popular among the seamen as a good-natured jolly fellow, and an amusing companion. He was not praticularly proud of his anesstry. a good-natured jolly fellow, and an amusing compa-nion. He was not particularly proud of his ancestry, and when his portrait was taken by Mr. Woolley, in 1866, for the Intercolonial Exhibition, he objected to the photographas being too black for him." He was, however, a pure bred Tasmanian aboriginal, and as black as a sloe. He was on the regatta ground in January, 1868, when the Duke of Edinburgh patro-nized that festival, and, attired in a blue suit, with a cold lace hand round his cap, he was presented to the gold lace band round his cap, he was presented to the

THE distilling industry in Holland formerly so flourishing, suffered a good deal from the civil war in America. The annual exports of hollands, called schiedam varies from 70,000 to 80,000 hectolitres. schiedam, varies from 70,000 to 80,000 hectoutres. The principal distilleries of Geneva are situate in the province of South Holland, were they are 328, employing about 2,000 workmen. The town of Schiedam alone has 226, with 600 to 800 workmen. Those employ steam power. The towns of Delit, Gondo, Rotterdam, and Lingden have also distilleries, but of less importance. At Delitshaven, near Enterbut of less importance. At Delftshaven, near Rotter-dam, there are 36 distilleries, which ship 26,400 hectolitres. The 25 distilleries of liqueurs in Amsterdam produce annually 14 million litres. In all the other provinces there are small distilleries to supply the local wants. There are besides, at Nimeguen, and at Voorburg, near the Hague, two perfume distilleries.

THERE was lately brought to M. Gosselin, at the THERE was lately brought to M. Gosselin, at the Hopital de la Charite, an infant five weeks old bearing at the end of the trunk an appendix five centimetres long, a little thicker than a goose-quill, and slightly tapering at the free end. The "British Medical Journal" states that on examination, M. Gosselin found it to be soft, and apparently not a prolongation of the vertebral column. He therefore, in compliance with the desire of the parents, removed it by two semielliptical incisions at the base. A rather large artery required ligature; the edges of rather large artery required ligature; the edges of the wound were brought together with metallic sutures; and healing, M. Gosselin has been in-formed, took place rapidly. On examination, the appendix was found to consist externally of a thin cutaneous sheath without heir and integrally on cutaneous sheath without hair, and internally an abundant fibro-cellular tissue, containing fat only at its junction with the subcutaneous connective tissue. The case was like one of "Molluscum pendulum," having the peculiarities of being congenital, of being more elongated than usual, and of being in a situation where it might readily be mistaken for a tail.

# Patents for Inbentions.

## ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronologic al order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these sbridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

ment:—
BOILERS AND FURNACES—3418, 3426, 3438, 3461
BUILDINGS AND BUILDING MATERIALS—3401, 3437, 3444
CHEMISTRY AND PHOTOGRAPHY—3390, 3393, 3412, 3459
CULTIVATION OF THE SOIL, including agricultural implements and machines.—3397, 3425, 3431, 3458
ELECTRICAL APPARATUS—3462
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3398, 3405, 3417, 3432, 3435, 3447, 3448, 3452
FOOD AND REVERACE Including Abs.

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—3388, 3414
FURNITURE AND APPAREL, including household utensils time-keepers, jewellery, musical instruments. &c.—3391, 3394, 3395, 3415, 3424, 3427, 3434, 3436, 3440, 3445
GENERAL MACHINERY—3387, 3399, 2403, 2409, 3420, 3421, 3439, 3456, 3460, 3463
LIGHTING, HEATING, AND VENTILATING—3392, 3343, 3441
3444

SHIPS AND BOATS, including their fittings-3341, 8455, 3465

STEAM ENGINES-3421, 3422 WARFARE-3408, 3433, 3435

3386 SIR J. MACNEILL, Knight, Kensington. Damping postage stamps. Dated November 7, 1868.

This relates first to the construction of portable cases or holders, corresponding in size with the postage or other adhesive stamps they are intended to hold, the depth of such cases depending on the number of stamps they are to contain.—Patent completed.

to contain.—Patent completed.

3:387 J. H. JOHNSON, Lincoln's Inn. Screw threads. (A communication). Dated November 7, 1868.

The feature of novelty is the employment of a travelling inclined plane, the angle of the incline being adjustable by means of a screw and adjusting nut, for the purpose of imparting the necessary longitudinal traverse to the screw blank or to the cutter, such travelling incline being moved forward in a guide, by means of a pinion in gear with a rack on the slide which carries the incline. This actuating pinion derives its motion from the mechanism which rotates the screw blank or cutter, as the case may be, so that the rate of motion of the incline along its guide is always in proportion to the speed of rotation of the screw blank or of the cutter, and hence a spiral or screw thread will be produced upon the blank.—Patent completed.

3388 J. STURROCK, Glasgow. Metallite caps. Dated No

3388 J. STURROCK, Glasgow. Metallic caps. Dated No.

3388 J. STURROCK, Glasgow. Metallic caps. Dated November 7, 1868.

This relates to an improved metallic caps to be applied to bottles or other vessels for the purpose of sprinkling in small quantities the liquids or fluids contained therein. The lower part of the cap is formed of thin flexible metal, for the purpose of being fitted to the neck of the bottle or other vessel; the ordinary cork or stopper is dispensed with, and a small ring of cork or other suitable material is placed between the mouth of the bottle or vessel and the upper interior part of the cap, for the purpose of forming a secure joint at this point. At the centre of the upper part of the cap a projection is formed, over which is screwed a secondary removable cap; the projection is perforated with one or more holes, through which the liquid is sprinkled as required.—Patent completed.

3389 A. M. CLARK, Chancery-lane. Planing metals, &c.

3389 A. M. CLARK, Chancery-lane. Planing metals, &c. (A communication). Dated November 7, 1868.

The invencer employs such new combination of parts, that the flywheel used in such machine may be dispensed with, substituting in lieu thereof a progressive diminution of the speed of the tool while traversing the space assigned it in the machine.—Patent completed.

assigned it in the machine.—Patent completed.

3390 A. M. Clark, Chancery-lane. Separating solid
matters. (A communication). Dated November 7, 1868.

The inventor subjects the liquid to a filtering process in
a closed vessel, under the pressure of a column of liquid
varying in height according to circumstances. A series of
apparatus is employed arranged with a view to multiply
the filtering surfaces. The filters are made movable, so as
to enable them to be readily replaced after each cleansing
of the apparatus, and permit of the operation being carried
on almost without interruption.—Patent completed.

3391 W. J. Chunke True. Washing lines. Dated No.

3391 W. J. CRIDDLE, Truro. Washing linen. Dated No. vember 7, 1869.

In the copper or other capacity in which the linen is boiled a perforated false bottom is placed, provided with a central vertical tube of suitable size, communicating with the space below the false bottom.—Patent abandoned.

3392 W. CORELESS, Datchet. Lamp globes and glasses.

Dated November 7, 1868.

The object is to so construct lamp globes and glasses as to concentrate the light from a burner all around, below the level of the light, whilst at the same time the direct passage of heat is arrested; also to afford facilities for making the light of any agreeable colour; and also to render the air of a room more agreeable by the evaporation of water. For this purpose the inventor employs a double cup-like glass, with a space between the two cups, which he fills with water. The outer cup is approximately a portion of a sphere, and the inner cup may also be of a similar form, or in some cases he makes it simply cone or funnel shaped. The inner cup is, by preference, composed of a series of plain or slightly concave surfaces rounded at the angles. The water filled into the space between the two cups prevents the transmission of heat downwards, and become slightly heated and slowly evaporates, thereby moistening the air, which in brightly lighted rooms is frequently unpleasantly dry.—Patent completed.

3393 G. T. BOUSFIELD, Brixon. Cooling and barriag soap.

3393 G. T. BOUSFIELD, Brixton. Cooling and barring soap.

A communication). Dated November 7, 1868.

This consists in introducing soap while in the hot and fluid state into metallic tubes, of the size and shape required for bars of soap, allowing it to congeal, and subsequently forcing out the soap in the form of a long bar, to be cut in lengths that may be required.—Patent aban-

to be cut in lengths that may be required.—Patent abandoned.

3334 N. WILSON, High Holborn. Sewing machines. Dated November 9, 1868.

This relates to that class of sewing machines known under the name of shuttle machines, or in any machines wherein an equivalent for a shuttle is used, such as a bobbin or reel shuttle, and consists in improvements upon a previous patent, dated February 14, 1868, in order to obtain a motion from the pinion shaft, to drive the lever, which drives the needle slide, the whole being a combination and new arrangement of parts. The arm which projects carries the needle slide. The driving wheel revolves on a stud, and is furnished with internal teeth in a recess, which drive the pinion which drives the shaft, to which is affixed the crank plate, into which is affixed to the bell crank. This bell crank reciprocates and moves on a centre pin; on the other limb of the bell crank is a hinge joint, on which hinges the reciprocating arm of the shuttle holder; carrying the shuttle. In front of the shuttle holder, carrying, fastened at the top end by a screw, and at the bottom end pressing against the arm of the bell crank, which forms the jaws of the hinge in which the shuttle holder works. When it is required to take out

the shuttle, the shuttle holder is brought over, when the shuttle can be taken out and replaced much easier than drawing out the shuttle in the ordinary way from the shuttle holder.—Patent completed.

3395 H. DAVIES and J. PARSONS, Birmingham. Cigar

3395 H. DAVISS and J. PARSONS, Birmingham. Cigar racks. Dated November 2, 1868.

The inventors mount the tobacco dish upon a central rod or pedestal, and support it upon a base plate or foot, as large as or a little larger than the dish. They prefer to make the base plate or foot of a concave figure. The base plate or foot is thereby made to constitute a shallow dish for receiving the cigar or tobacco ash. They provide the tobacco dish described with an overhanging rim, situated at right angles to the axis of the dish, and convert the said rim into a rack for receiving cigars and spills.—Patent abandoned.

3397 R. M'HARELY, Edinburgh. Hocing land. Dated November 9, 1863.

This consists of a shaft or bar, mounted on a pair of wheels at one end, whilst at the other end a handle is placed, by which the operator actuates the implement. At a short distance from the part to which the wheels are attached an adjustable guide socket is placed, in which is held the hocing tool, which is arranged to be capable of adjustment in any required position, according to the nature of the work to be done.—Patent abandoned.

3398 B. HUNT, Lincoln's Inn. New fabric. (A communication). Dated November 9, 1868.

This consists, principally, in the novel combination of a woven fabric, in which the warp threads are of any ordinary fibrous material or metallic threads, and the weft of fibres of the aloe, more commonly called manilla or vegetable silk.—Patent abandoned.

vegetable silk.—Patent abandoned.

3399 W. M. Brown, Paris. Man engines. (A communication.) Dated November 9, 1868.

The object is to utilize the man engine ordinarily employed in lifting the miners as a means of lifting the water of the mine during the time the man engine is otherwise unemployed. For this purpose to each shaft of the lifts of the man engine is attached a series of tipping buckets, which, alternately with each stroke of the lifts, are emptied and filled into each other, thus with every stroke of the one lifting all the water in the buckets of one stage, and discharging their contents into the buckets of the other lift when at its lowest point of stroke, and with each stroke discharging one bucket of water at the day level or ground level of the mine.—Patent completed. completed.

3400 P. E. DE WISSOCQ, Paris. Lead ores. Dated November 9, 1869.

This consists, first, in converting lead ores into chloride by treating them with hydrochloric acid. Second, in dissolving the chloride in water and allowing it to remain in contact with wrought or cast iron, or, better still, upon iron sponge, which decomposes it, precipitating the lead in a metallic state, and forming chloride of lead. Third, in collecting the precipitated lead and melting it in a furnace or in a pot, and then casting it into pigs. Fourth, in collecting the two secondary products which are formed, and which are sulphuretted hydrogen and chloride of iron. Fifth, when the mineral contains silver, in treating with a boiling and concentrated solution of salt the insoluble residue which is left after all the chloride of lead has been dissolved. Sixth, in precipitating by copper the chloride of silver dissolved in the preceding operation. Seventh, in employing either hyposulphite of sods or any other body having the property of dissolving chloride of silver, in place of see salt, for dissolving the chloride of silver, in place of see salt, for dissolving the chloride of silver.—Patent completed.

3401 W. R. Lake, Chancery-lane. Door handle. (A

silver.—Patent completed.

3401 W. R. LAKE, Chancery-lane. Door handle. (A communication.) Dated November 9, 1868.

This consists, chiefly, in the employment of a spring setting into a ratchet cut on the knob spindle. This spring is fitted in a chamber formed in the spindle sperture of the knob or handle, and ratchet teeth are formed on one side of the spindle, at one or both ends, a longitudinal aperture being formed or left at that part of the spindle in which the said teeth are cut in order to permit of the spring being forced out of the teeth when the handle or knob is required to be placed nearer the end or withdrawn from the spindle, and near the working or loose end of the spring, to permit of the insertion of a bradawl, or other simple instrument that will pass through the aperture or slot, and press against the said loose end of the spring, in order to force the latter from the teeth, and thereby relax the said knob.—Patent completed.

3403 H. L. BENNISON, Greenwich. Rotary engine. Dated

3403 H. L. BENNISON, Greenwich. Rotary engine. Dated

3403 H. L. BENNISON, Greenwich. Rotary engine. Dated November 10, 1868.

This consists in constructing the engine with a four-way cock, for working supply and exhaust or waste, and in the special construction of the cock, by so altering the form of the section of the passage way of each arm in the length of the arm, and proportioning the ways through the plug as to avoid the construction which ordinarily occurs in four-way cocks. With this object the form may be circular at the extremities of the arms, and thence taper or change up to the plug seat, where the size may be diminished as presented against the cross section of the plug, and enlarged in the direction of the side or length of the plug, which, it is believed, will afford the means of constructing the cock with a plug of less diameter than heretofore, and though it may be only partially opened to admit steam, water, air, &c., will allow of a free and rapid exhaust.—Patent completed.

3405 T. Rose and R. E. Gieson, New Brighton. Utiliting

admit steam, water, air, ac., will allow of a free and rapid exhaust.—Patent completed.

3405 T. Rose and R. E. Gibson, New Brighton. Utilizing cotton waste. Dated November 10, 1868.

When fibrous cotton is treated or broken up by machinery to liberate the kernels, there is left, after the kernels (usually in a mealy condition) have been sifted out a waste material not hitherto utilized, consisting of the husks and fibre. This material forms a considerable proportion of the whole weight of the seed, and it is the object of this invention to utilize it in two important manufactures, viz., the fibre in the production of paper stock to be used in the fabrication of paper, and the husks in oil cake for feeding cattle. In carrying the invention into effect, the inventors first proceed to separate the husks from the fibre, as far as possible. For this purpose they moisten the whole material with water, and after it has laid for about twenty four hours, subject it to a disintegrating or tearing action, and to a sifting motion. This treatment removes all, or nearly all, the inner, and a large portion of the outer husks.—Patent completed.

3408 J. CLARK, Strand, W.O. Explosive compounds. Dated November 10, 1868.

This relates to improvements in the treatment, manufacture, and use of explosive compounds, which may be divided into the following parts, namely, first, a new mode of treatment in manufacturing pyroxyline, whether in the form of gun cotton, gun cloth, wood powder, or any other explosive compound, produced by treating vegetable there with mixed nitric and sulphuric acids. Second, the formation of explosive compounds into pellets or compressed charges. Third, an improved mode of applying glycerine oil in combination with other substances, for the production of an explosive compound.—Patent completed.

3409 J. HINE, Cockermouth. Millstones. Dated Novem-

3409 J. Hing, Cockermouth. Militaines. Dated November 10, 1869.
This consists in a rectangular frame having a longitudinal opening or slot, in which works the block containing the diamond or other cutter. This frame is firmly attached by means of a nut working in a slot at one end of said frame to a radial arm pivoted at the centre of the millstone, so as to turn freely.—Patent abandoned.

minisone, so as to turn freely.—Patent abandoned.

3410 C. E. and F. C. Winbr, Cardiff. Preenting collisions. Dated November 10, 1868.

The signal which is to be dropped on the line by a train is intended to burn for a greater or less length of time, for the protection of the train in advance. It consists of a paper or other case or cartridge filled with combustible matter, and terminating in a suitable fuse, to be ignited by friction or otherwise.—Patent abandoned.

8411 J. H. WILSON, Liverpool. Ships' waterclosets. Dated

2411 J. H. WILSON, Liverpool. Ships' waterclosets. Dated November 10, 1868.

Ships' waterclosets are constructed with dry wells or cisterns to receive, after use, the contents of the closets, so that the same may be emptied, when necessary, by force or lift-pump arrangements, or by compressed air arrangements, or other suitable means whereby the contents of the cistern or dry well may be emptied at the required height. The cistern or dry well into which the closet discharges is provided with a pump with discharge or nozzle coming through the sides of the ship or vessel, and with an air pipe leading from the cistern and opening also through the sides of the ship for the purpose of preventing accumulation of gas.—Patent completed.

8412 J. GREGORY, Kingswood. Retorts. Dated Novem-

3412 J. GEEGOEY, AIRGRAUGH. ALLERS. DESCRIPTION.

ber 10, 1868.

The retort is constructed by fixing a perforated internal cylinder inside a larger external cylinder by means of suitable projections attached to the outside of the internal cylinder, which are made to slide in longitudinal grooves, attached to the inside of the external cylinder, so that the two cylinders are held fast, and are made to rotate together.—Patent abandoned.

ther.—Patent abandoued.

3413 W. H. HALL and J. COOKE, Birmingham. Safety lamps. Dated November 10, 1868.

The burner is made by first cutting a shell for the bottom part, and this is made so that it can be screwed to any ordinary Stephenson lamp in place of the common burner screw. On the top part of this shell is placed a diaphragm, which contains or to which is fastened the wick tube. The diaphragm is raised in the centre to allow space for the pinions or small wheels to be worked for raising or lowering the wick; over this diaphragm and wick tube is placed a cone, which has an opening at the top for the flame to protrude, and several holes at the bottom to feed the flame. The wick tube is flat, and reaches to the top of the dome; the parts of the burner are fastened together at the centre, and the pinions with the spindle for raising the wick are placed in their respective positions at the time.—Patent abandoned.

3414 T. CAIN, Douglas, Treating potatoes. Dated No-

tive positions at the time.—Patent abandoned.

3414 T. CAIN, Douglas, Treating potatoes. Dated November 10, 1868.

After cooking the potatoes in the usual manner, the inventor causes air to be passed through and between them for the purpose of carrying off any water or steam that may be on or between them, and so prevent it from being mixed with the potato. After the steam or water is entirely driven off by the current of air, he passes the potatoes between two rollers, one of which has a plain or solid surface, and the other is covered with wire cloth or similar material. As the potatoes pass between these solid surface, and the other is covered with wire cloth or similar material. As the potatoes pass between these rollers, they are pressed in through the wire cloth into the interior of the roller which is covered with the wire cloth, leaving the skin on the surface of the wire cloth, whence it may be removed by hand or otherwise.—Patent

abandoned.

3415 J. Hickisson, Hackney. Marking lines. Dated November 10, 1868.

This consists in manufacturing a pencil of a composition of materials, such as are mentioned below, which will fuse, melt, or dissolve in such manner that the mixture, when fused, melted, or dissolved, may be run or cast into moulds of a desired form, and may be set or hardened therein. The composition in this condition will be fit for writing or marking purposes. The following are materials and proportions preferred:—Nitrate of silver, 100 parts; nitrate of potash, 100 parts; black platinum, 20 parts.—Patent completed.

Patent completed.

3416 C. J. Abbott, Harrogate. Distributing seeage scater.
Dated November 10, 1862.
The centre portion of the apparatus consists of two lightly constructed wheels capable of revolving upon a perforated tube which constitutes the axle. The ends of the tube project from the wheels, and are provided with flanges for the purpose of connecting additional perforated tubes thereto, and by means of which the range of the apparatus can be extended as desired, such additional perforated tubes being supported at their extremities by wheels, each of which revolves upon a short hollow axle, the same being loose and flanged on each side of the nave. The axle of the central portion of the apparatus is furnished with projecting bars from which strengthening ropes of wire or other suitable material may be extended to the extremities of the additional tubes for the purpose of keeping them in position, such ropes being tightened by means of any suitable contrivance.—Patent completed.

3417 W. Riddle, Larkhall-lane, S. Hooping bals.

of any suitable contrivance.—Patent completed.

3417 W. Riddle, Larkhall-lane, S. Hooping bales.
Dated November 10, 1868.
This relates to the method of hooping or bending bales by forming loops at the ends of the hoops which encircle the bale, and passing a stiff lath or spear through such loops, as described in the specification of a former patent, dated May 8, 1862 (No. 1876). The ends of the hoops on a bale are brought side by side, and the spear or lath is passed through the folded ends or loops. When the presents

sure is released from the bale, the hoops are not dependent on the elasticity of the bale for holding on to the spear, as the inner fold tightens on the spear with the strain. The spear should fit tolerably well, and it is preferred to bend the hoop red hot.—Patent completed.

the hoop red hot.—Patent completed.

3413 T. R. Crampton, Great George-street, S.W. Furnaces for liquid furt. Dated November 10, 1863.

The inventor burns the oil in a close furnace, into which he forces, by means of a fan, and at a comparative light pressure, the bulk of the air required for the combustion of the liquid. For this purpose he admits the creesote, or other combustible liquid to be burnt, into the jet or stream of air as it passes from the conduit pipe into the furnace or combustion chamber, and for this purpose he inserts the oil supply pipe into the top of the conduit pipe, in close proximity to the furnace, or just in front of the end of the conduit pipe. The liquid may enter into or in front of the air pipe in one or more streams. The invention also consists in employing solid fuel in combination with liquid fuel, by blowing the solid fuel in the form of dust into the furnace, as described in the specification of a patent, dated August 13, 1868 (No. 2539). The solid and liquid fuel may be introduced at the same orifice, or separately. By burning liquid fuel in combination with the solid fuel, perfect combustion of the solid fuel is more readily obtained.—Patent completed.

3119 H. BESSEMER, Queen-street-place, E.C. Cast steel

readily obtained.—Patent completed.

3419 H. BESSEMER, Queen-street-place, E.C. Cast steel and malteable iron. Dated November 10, 1863.

The chief object sought to be obtained by means of this invention is a more rapid and less expensive mode of fusing malleable iron and steel of different kinds, and obtaining cast steel and homogeneous malleable iron therefrom. In order to accomplish this the inventor avails himself of the property of gaseous fluids to rise in temperature in proportion as they are compressed, and he constructs furnaces of sufficient strength to withstand an internal pressure equal to two or more atmospheres, and retains in such furnaces the products of combustion under such an excess of pressure over that of the external air as will produce the high temperature necessary for rapidly fusing malleable iron and steel of any kind or quality.—Patent completed.

3420 T. VATGHAN and E. WATTEEU, Middlesborough.

nanty.—I ment compresent.
3420 T. VAUGHAN and E. WATTREU, Middlesborough.
crew botts. Dated November 11, 1868.
The inventors form the front or screwed end of the bolt Screw bolts.

The inventors form the front or screwed end of the bolt hollow, or with a recess passing some distance down the centre of the bolt, and when the nut is screwed up to the required degree of tightness they force a steel conical plug or mandril into the opening of the recess, so as to widen out that part of the bolt projecting beyond the nut, which is thus prevented from unscrewing. The steel mandril is then removed and employed in the same manner for other bolts.—Patent completed.

manner for other boits.—Patent completed.

3421 E. and F. DIXON, Cliptone-street, W. Packing boxes. Dated November 11, 1868.

This consists in an arrangement of springs and guides of metal and india-rubber, or other flexible substances, which are made to form compartments in number and size, according to requirements, and at the bottom of each compartment there is an elastic frame, grating, or spring substance, which secures the neck of the bottle, and the sides or griders hold the bottle in an erect position, and so firmly that no jarring can shift the bottle.—Patent abandoned.

3422 R. HALLIDAY Worsley. Oling area. Dated

Patent abandoned.

3422 R. HALLIDAY, Worsley. Olling axles. Dated November 11, 1863.

This principally consists in placing a trough or receptacle containing oil between the rails and below the level of the same, such trough or vessel being provided with a small force pump and four branch pipes extending upwards and outwards, and having at their ends small mouthpieces or jets which convey the oil to all four axle boxes at once.—Patent completed.

moutapieces or jets when convey the oil to all four axis boxes at once.—Patent completed.

3423 E. Mader. Swanses. Manufacture of tin plates. Dated November 11, 1868.

The object of this invention is to impart to black plates (whether composed of iron or steel) an even coating of tin or other metal, or a mixture of easily fusible metals. The plates are passed through a bath of molten metal covered with any suitable flux to prevent oxidation and assist in the union of the coating metal with the iron or steel plate. Or a plate already coated in any of the ordinary ways is passed through the machine to finish it. Each plate is guided into, through, and out of the bath by means of driven rollers and guide bars. The delivering reliers, or the last pair (if more than one pair is used), are so arranged with respect to the level at which the metal is to be maintained as to ensure that the bite of these rollers shall be below the surface of the metal, and these rollers may be formed with annular grooves to allow of the metal flowing freely to the plate.—Patent abandoned.

3124 W. S. Thomson, Cheapside. Corset, &c. Dated

3424 W. S. THOMSON, Cheapside. Corsets, &c. Dated November 11, 1868.

The inventor employs felted cloth as it comes from the

November 11, 1868.

The inventor employs felted cloth as it comes from the fulling mill or previous to its being stretched and finished for the market, or he manufactures felted cloth tubes especially for the purposes of this invention, his object being to obtain a woollen material that will admit of being moulded to the required shape, and which, when moulded, will retain the shape it has received. The fulled cloth, or partially manufactured material, is saturated with water, and in this state is applied to a metal mould or former the shape of which it is required to receive and retain.—Patent completed.

8 3425 M. H. DAVIES, Liverpool. Wire fences. Dated November 11, 1868.

In order to strain the wires of fences, the inventor arranges the straining posts with winders constructed as follows:—Each winder consists of anaxis passing through the two checks of the posts, and capable of turning therein. On one of the checks, around the hole which receives the axis, a toothed ring is formed, or the toothed ring may be otherwise fixed. The winding barrel has in connection with it a ring of internal teeth; they are formed inside a flange upon the barrel. The ring of internal teeth surrounds the fixed ring of teeth, and contains an additional tooth or teeth. The barrel is mounted upon an eccentric, formed upon the axis, on which it is able to turn, and the throw of the eccentric is such that, as it revolves, it brings the internal ring of teeth to gear with the fixed ring on every side in succession, and so, at each rotation of the axis, the barrel is turned the space of one or more teeth.—Patent completed.

8426 C. and J. Wilson, Hanley. Brick Films. Dated November 11, 1868. November II, 1868.

In order to strain the wires of fences, the inventor arranges the straining posts with winders constructed as follows:—Each winder consists of anaxis passing through the two checks of the posts, and capable of turning therein. On one of the checks, around the hole which receives the axis, a toothed ring is formed, or the toothed ring may be otherwise lixed. The winding barrel has in sonnection with it a ring of internal teeth; they are formed inside a flange upon the barrel. The ring of internal teeth surrounds the fixed ring of teeth, and contains an additional tooth or teeth. The barrel is mounted upon an eccentric, formed upon the axis, on which it is able to turn, and the throw of the eccentric is such that, as it revolves, it brings the internal ring of teeth to gear with the fixed ring on every side in succession, and so, at each rotation of the axis, the barrel is turned the space of one or more beth.—Patent completed.

3426 G. and J. Wilson, Hanley. Brick kilns. Dated November II, 1868.

The inventors make a number of openings about half

way up the kiln, through the external walls thereof, for the admission of cold air into the bags at or about the centre of the kiln, whereby they obtain greater courtol over the heat and prevent the formation of smoke. Three perforated "quarries" or fire-brick lumps or slabs are employed, placed one behind the other, and standing over the inner arch of the fire-hole. These perforated quarries further assist in preventing smoke, and serve to keep the fire to the bottom of the kiln. Extending straight down from the outer perforated quarry or brick above referred to is the regulator hole or passage, which communicates with a perforated hot and cold air chamber, immediately above the fire-hole. This regulator hole and chamber are for facilitating the supply of fuel to the fire-hole, and for admitting hot and cold air thereto. The front of the fire-hole is perforated with numerous holes, leading into various parts of the fire-hole, and supplying air thereto for keeping up an uniform and active combustion.—Patent completed.

3221 F. HOLMES, Marks Gate, Essex. Pipes for smoking.

3427 F. HOLMES, Marks Gate, Essex. Pipes for smoking.

3427 F. HOLMES, Marks Gate, Essex. Pipes for smoking. Dated November II, 1868.

This consists in making an orifice at the end of the pipe in continuation of the tube, and fixing a plug therein, which is made removable for the purpose of cleaning.—Patent abandoned.

3428 G. PIERCY, Halifax. Safety stay for carriages. Dated

3428 (A. Piercy, Halifax. Safety stay for carriages. Dated November 11, 1568.

In constructing a safety shaft stay, the inventor joints one end of a flat bar or piate of iron, hereinafter called the stay, to the outer wheel iron of the shaft by means of the bolt commonly called the "dragon tongue" bolt, the said stay being capable of turning in a vertical plane upon the said bolt. The other end of the stay is connected to the shaft, at the distance of a few inches from the shaft bolt, by means of a light collar bolt. The said collar bolt works in a slot in the end of the stay, the head of the said collar bolt works in a slot in the end of the stay, the head of the said collar and curved washer bearing against the inner side of the said stay.—Patent abandoned.

3429 J. Lewethewatte. Bury. Wood-shaping machinery.

said stay.—Patent abandoned.

3429 J. Lewthwaite, Bury. Wood-shaping machinery.
Dated November II, 1868.

The inventor uses cutters of various kinds fitted to the
machines, putting them in motion by animal, steam, or
other power, with the requisite degree of rapidity, and
the form to work by is produced by a metal, wood, or
other pattern or cam, which revolves either on a vertical
or horizontal axis, and thus guides the article to the
cutters in a similar form, the pressure against the cutters
being induced by a descending weight or weights, or by a
spring or springs, so arranged that the cutters only work
with the grain, one cutter working till it reaches the cross
grain, when it ceases to cut, and the work is taken up by
the opposite cutter, which thus works with the grain, and
a similar smooth surface is produced without what is
called splintering.—Patent abandoned.

3430 A. M. Clark, Chancery-lane, W.C. Cylinder print-

34:30 A. M. CLARK, Chancery-lane, W.C. Cy'inder printing machines. (A communication). Dated November 11, 1868.

According to these improvements, first, either movable According to these improvements, first, either movable characters or stereotypes may be employed in the same machine; second, both sides of the sheet may be printed at one time, by disposing two printing surfaces on the cylinder; and, thirdly, a continuous sheet or row of paper is employed, each roll answering the purpose of a gauge. The improvements may be employed either separately or in combination.—Patent completed.

The improvements may be employed either separately or in combination.—Patent completed.

2431 C. J. CHAPLIN, Bucklersbury. Cattle food. (A communication). Dated November 12, 1868.

After the operation of making and the completion of the fermentation, usual in the process of distillation from raw or malted grain, vegetables, or otherwise, it is proposed to separate the fluid portion of the wash, beer, wine, or cider from the grains or solid matter, by passing the same through a hair or other strainer, arranged for the purpose, after which the solid matter is subjected to gentle pressure, either by passing the matter through rollers or their equivalents, to rid it of the greater proportion of moisture. It is then passed into a tub or other vessel, furnished with an agitator. In this vessel is added to the mass a proportion of linseed meal, peas, meal, bran, or other farinaecous material, also aromatic substance. The ingredients are then thoroughly mixed or incorporated by the motion of the rake or agitator. The material is then transferred, either in bags or otherwise, to a press, and subjected to sufficient pressure to express the remaining fluid, and to form it into solid cakes. This may be accomplished by hydraulic pressure or otherwise, as may be most desirable. The cakes so pressed are then subjected to a stove heat in a kilu or room, arranged for the purpose of removing any remaining moisture.—Patent abandoned.

3432 S. and G. HOLT, Bacup. Pickers. Dated Novem-

3432 S. and G. HOLT, Bacup. Pickers. Dated November 12, 1868.
This relates to pickers employed in connection with looms for weaving, which are made of buffalo hide, and consists in forming them, in the first part of the process, open at the top, and then introducing a hollow top, or barrel of metal, or other suitable material, betwixt the two cheeks, or those parts through which the spindle holes are made, with a rivet passed through the said checks and hollow top to secure the same together. It is preferred to have a flange or collar at each end, which may be either cast or formed on the barrel, or added to it, as in using plain tubes, having a washer at each end, or the rivets may be formed with flanges or collars or shoulders thereon.—Patent abandoned.

8434 A.O. HELY, Stratford, E. Umbrellas, Dated No-

8434 A.O. Helly, Stratford, E. Umbrellas. Dated November 12, 1863.

This consists in so fixing the covering of an umbrella, sunshade, or parasol, to the frame, that it may be removed and refixed or replaced by another covering at pleasure, instead of being permanently fixed to the frame. This is effected by fastenings attached either to the covering or to the frame, or to both, whereby, without interfering with the present action of the parts, the one may be securely fixed to the other, and yet admit of being easily taken apart when desired.—Patent abandoned.

when desired.—Patent abandoned.

3435 T. B. COLLINGWOOD and W. HARDMAN, Boch dale Spindles and Hyers. Dated November 12, 1868.

This consists in arranging to radiate from a centre as many separate cutters as there are threads to be cut, so that such cutters can be simultaneously adjusted by a cone or other means, to and from the centre from which they radiate, and in cutting the threads on the spindle, by causing these cutters to rotate and advance at the same time against the spindle which is fixed, or in giving these screen movements to the spindle, the cutters being fixed, or in giving one movement to the spindle and the other to the cutters.—Patent completed.

2436 P. J. Lysky Manchester. Secting machine. (A

giving one movement to the spindle and the other to the cutters.—Patent completed.

3436 P. J. Livsey, Manchester. Seving machine. (A communication). Dated November 12, 1868.
This consists, first, in an upward manner of constructing the combination crank motion, and relates to a previous patent, dated January 2, 1865, No. 2. Second, in a peculiar arrangement of lever and link, in combination with the needle bar of a sewing machine and two stationary guides, by which the thread is controlled in making stitchea, and the quantity is regulated to suit thick and thin goods. The fulcrum of the said lever is adjustable on the presser har, or it may be fixed in the face plate, and the said link is jointed to the lever and needle bar. The thread to be regulated passes through a hole in the end of the lever. Third, in an arrangement of the shuttle driving mechanism, whereby greater durability, simplicity, and economy of construction is obtained; motion is taken from the rear, and of the upper shaft to give oscillation to a shaft below the table, upon the front end of which shaft there is an arm, having a rod socketed in it, with a partially round end that fits a part in the shuttle driver, which slides in a straight race, and is kept down by a plate secured by screws. Fourth, in an improved manner of suspending the feed wheel or device, and of raising and lowering the same when it is desired to sew thick or thin material which is accomplished by mounting the feed wheel or device upon a crank shaft, having a lever or arm on it, by moving which in one direction the feed is raised for thick material and in the other direction is to lowered for thin material.—Patent completed.

3437 D. Griffiths, Bradford, Yorkshire. Timber bearers.

2437 D. GRIPFITHS. Bradford, Yorkshire. Timber bearers.
Dated November 12, 1868.
This consists in cutting or removing the needless wood at certain angles from the extremities of a timber bearer, and placing the same in a central position to sustain the chief pressure.—Patent abandoned.

3438 W. R. GRIFFITHS, Bristol. Boilers. Dated Novem-er 12, 1868.

ber 12, 1868.

The inventor constructs the main part of the boiler in the form of a waggon boiler, and the firebars may be either solid, as usual, or made tubular, so as to contain water which will be heated by the incandescent fuel thereon. These firebars, if tubular, may be connected either at one or both ends with the main water chamber. Immediately above the fireplace there is another set of tubular bars also connected at one or both ends with the water space of the boiler. The heat from the fire below will act on these water tubes, and quickly generate steam, but in order to prevent the heated gases from passing between the tubes without giving off their caloric, flat iron plates are placed on the tubes, but space is left at the rear or inner end to allow the smoke and gases to pass up to the space above the tubes, and from thence out at the front of the boiler to a flue space above.—Patent abandoned. Patent abandoned.

3439 L. WRAY, Ramsgate. Crushing quarts. Dated lovember 12, 1863.
The crushing and grinding instrument is formed with urved surfaces, and is made to vibrate or oscillate on a centre.—Patent abandoned.

curved surfaces, and is made to vibrate or oscillate on a centro.—Patent abandoned.

3440 E. Haas, Mark-lane, E.C. Sewing machines. Dated November 12, 1863.

This relates to that class of sewing machines in which a single thread is used. The inventor employs a needle formed with a spring beard, similar to the beard of the needles of knitting machines; he also employs the needle to effect the feeding forward of the fabric. For this purpose the needle passes through a guiding hole in a plate which is held at a short distance above the table or plate, on which the fabric or work rests, whilst the upper end of the needle is fixed in a holder carried by the pin of a crank, which is on the end of the driving axis. The thread from the reel is led through a loop or coil of wire, which is fixed to the under side of the table of the machine just at the side of the slot therein, down through which the needle passes. When the needle has passed down through the work and through this slot, its lower end is by the movement of the crank moved sideways, which not only gives the forward feed to the work but swings the lower end of the needle from one side of the loop or curl of wire to the other. The thread which is lying in this loop is thus laid into the beard of the needle; as the needle again rises the beard is closed by its being brought against a fixed edge.—Patent completed.

3441 W. Donisthore, Trinity College, Cambridge.

fixed edge.—Patent completed.

3441 W. DONISTHORIES, Trinity College, Cambridge.

Getting coal. Dated November 12, 1868.

The inventor arranges the apparatus in such manner
that during the outward stroke a vacuum is produced by
the direct admission of the compressed air to the air
cylinder. The inward or cutting stroke is then produced
by means of this vacuum, aided by the expansion of the
compressed air from the inner end of the cylinder to the
outer end or ends of the same, or of another cylinder or
cylinders. In this way the waste of power which results
from allowing the compressed air to escape without previous expansion is avoided.—Patent completed.

3442 G. P. WHITE, Furnival's Inn. W.C. Scree piles.

vious expansion is avoided.—Patent completed.

3442 G. P. White, Furnival's Inn, W.C. Scree piles.
Dated November 12, 1868.
The shoe or foot is made with a thread of wrought from or wrought steel, in place of cast from. The thread may conveniently be a disc of sheet metal, with a hole in the centre and a radial slit cut from the centre to the circumference. The disc thus prepared is opened so as to form a screw of the desired pitch, and it is combined with a

boss to fit on to the end of the pile or post. This boss may be of cast iron, and then the wrought metal thread formed, as above described, may be placed in the mould and the boss cast upon it. Or the boss may be made in two parts or rings, separately fixed upon the pile or post, and holding the screw thread between them. Or the boss may be made in one piece with a spiral groove on its periphery, which receives the wrought metal thread, and the thread may be secured in the groove by a stop fixed in the groove behind it.—Patent completed.

3443 J. KRLIGE Tremadon North Welse. Cutting met.

the thread may be secured in the groove by a stop fixed in the groove behind it.—Patent completed.

3443 J. Kelloe, Tremadoo, North Wales. Cutting rock.
Dated November 12, 1863.

The machinery carries worm drills or borers, or rotating cutters. For boring, drilling, or making incisions, and also chiesel cutters or similar cutters. At the front of the machiner ear a number of worm drills or boring cutters, consisting of threaded or wormed rods or shafts, terminating in cutters which, preferably, are spear heads, or lance heads, or angular cutters. Cutting heads may be used alternating with each other, one cutter having sharp lateral angles protruding at the sides noxt which the edge of the next cutting head is straight or does not protrude, and so on. The drilling cutters are so mounted that one shall present its flat side to the surface to be cut, while the next presents its edge, and so on alternately. These drilling or boring cutters fit at their inner ends into collars or sockets, whence they are readily removable when out of action. They are supported on a frame capable of being slidden to and fro in a stationary frame. Such slidling action is effected by a worm actuated from the main driving shaft. They are also supported on two stout shafts resting on the main framework. Rotary motion is impacted to them by small philons or worm wheels, driven by a worm worked by gearing from a main driving shaft.—Patent completed.

3444 E. Owen. Blackheath. Night-light cases. Dated

3444 E. OWEN. Blackheath. Night-light cases. Dated November 13, 1868.

November 13, 1988.

The cases are impregnated in the course of their manufacture with tungstate of sods, phosphate of ammonia, borax, or other of the well-known materials, or compounds now used for rendering dresses and other fabrics fireproof.

—Patent abandoned.

—Patent abandoned.

3445 W. Thomas, Cheapside, E.C. Boots. Dated November 13, 1863.

The outer sole of the boot or shoe shape has a channel cut in the grain side round the edge to receive the sewing. To the inner or flesh side a strip of leather, about fin. wide is sewn along the said channel, with its outer edge corresponding to the edge of the sole. This welt is wetted and turned up at right angles close to the line of stitching, or the welt may have been previously damped and turned up before being sewn to the sole. The sole with the welt attached is fastened with its grain side to a last with the welt projecting. The upper, turned inside out, and having the stiffener in its place, is lasted and tackled, or lasted to the welt, and is then sewn to it. The welt and upper are now pared, and made to lie smooth on the sole; the last is withdrawn, the boot turned with its right side outwards, the inner sole and last put in, and the boot finished as usual.—Patent completed.

3446 B. P. Walker. Wolverhampton. Forging metals.

wards, the inner sole and last put in, and the boot finished as usual.—Patent completed.

3446 B. P. Walker, Wolverhampton. Forging metals.
Dated November 13, 1868.
This consists in the application of a copying principle to forging machines, such as those known as Rydor's forging machines, such as those known as Rydor's forging machines, or modifications thereof. A bolt or ram is employed, driven by a crank shaft and flywheel, as in the well-known Ryder machine, but in lieu of attaching a swage or die immediately to the lower end of the bolt, a lever is attached thereto, having its fulcrum at one end and a hammer face at the other, whilst it is attached to the bolt or ram at a point intermediate between the hammer face and fulcrum by a cross pin or suitable joint, so that the hammer face has a greater amount of motion than the ram. The fulcrum end of the lever rests upon a model or pattern, consisting of a piece of steel or other material, which is movable, and is shaped in accordance with the article to be produced.—Patent completed.

3447 J. DENDY and J. H. W. Biggs, Manchester. Arrangements of warps. Dated November 13, 1883.
This consists in an improved system of splitting the sheet of warp, in the sizeing or dressing machine, into several separate and distant warps, and in the arrangement and construction of improved warp or yarn beams, for sizeing or dressing machines, looms, and similar purposes.—Patent completed.

3443 R. A. Dalton and G. Barton, Coventry. Upholstery

2449 R. A. DALTON and G. BARTON, Coventry. Upholstery trimmings. Dated November 13, 1863.

The object of the invention is to manufacture these trimmings with fast edges or selvages, so that the edges will always remain perfect. For this purpose the inventors manufacture trimmings in a ribbon boom, and employ as the materials silk, worsted, and cotton, whereby the patentees obtain an upholstery trimming woven of the said materials with a fest adres on both sides. Pater comtees obtain an upholstery trimming woven of the said materials, with a fast edge on both sides.—Patent com-

pleted.

3449 C. E. BROOMAN, Fleet-street, E.O. Wall hangings.
(A communication). Dated November 13, 1863.

This consists in producing or effecting the painting or colouring upon metallic foll, by preference the foll. The inventors take thin the foll which possosses great flexibility. He spreads it upon a hard smooth surface, such as glass, taking care to damp the glass, in order to facilitate the spreading and retention of the foll. The foll thus spread constitutes a very smooth surface, on which he paints or colours in oil, either plain or ornamental, as on walls or wainscots. The inventor now allows the colour to dry and varnishes it. This portable painting, when removed from the glass with its lining of tin, is ready to be applied in a house or otherwise.—Patent completed.

3450. I Stephens Ryderstreet S.W. Carriage. Dated

3450 J. STEPHENS, Ryder-street, S.W. Carriages. Dated

November 13, 1863

November 13, 1863.

The inventor forms the attachments by means of vulcanized india-rubber, or othersprings; so long as the carriage is moving straight forward on even ground the spring attachments act simply as ropes, carrying the bearers over the wheel, and laying them in front in its course, but in passing over uneven ground, or round curves, they extend or contract, so as to let the bearers take a firm position on the ground without throwing undue strain on the connection.—Patent completed.

cylinder. Upon this cylinder they mount a sliding head, this head being made taper or conical at the outside, to suit the solidity they intend to give to the sand in the mould. This conical sliding head is fixed or attached to a strong crosshead. This crosshead is attached to a screw, which screw is fixed concentric with the cylinder and the moving head. The end of the screw is so constructed that it can be readily driven by gearing situated below the ordinary floor line. This screw is made to travel at such a speed that the loose head rises as the sand is being fed in at the top of the mould, so that the necessary solidity will be given to the sand. When this loose head has been raised to the length required, or, in other word, when the length of mould required has been made, then the cylinder is removed with its screw and loose head, and the mould taken into the stone, and the process repeated.—Patent completed.

3452 T. and A. T. Lawson, Leeds. Carding engines.

Patent completed.

3452 T. and A. T. Lawson, Leeds. Carding engines.
Dated November 13, 1868.
This consists, first, in making the shell of carding engine cylinders of wrought iron, either rolled or welded in one cylindrical piece. The shell thus made is connected with the ends of the cylinder, which are fixed on the axis by flanges and belts, or in other convenient way, or the shell may be made of severel such pieces. In making a carding engine cylinder of a number of drums or pulleys fixed on a shaft, the pulleys having cast-iron runs or shells, and hollow wrought-iron rims or shells and hollow wroughtion arms, and are thus carried by the axis, independently the one of the other.—Patent abandoned.

the one of the other.—Patent abandoned.

3453 C. MARKHAM and W. KNIGHTON, Chesterfield Moulding and drying moulds. Dated November 13, 1863.

The moulds for pipes or cylinders are formed in boxes suspended from the outer rim of a turntable, and, when moulded, the table is turned to bring them into a stove, which forms about half the circumference of one side of the circle, and the slide is shut across at either end of the stove between the suspended pipe boxes, and thereby about half the turntable with the pipes on the outer rim are enclosed in the stove, and the other half of the turntable remains open to the shop, wherethe moulding process is carried on; the moulds are thus swung into the stove upon the turntable upon which they are moulded.—Patent completed. completed.

completed.

343 R. A. Gold, Birmingham. Cabs. Dated November 13, 1863.

The inventor places the door at the back of the body of the carriage or cab, this door opening outwards, and he arranges the driver's seat at the front of the carriage or cab and on the roof theroof. The axle he places near the front of the body, and directly under the driver's seat. The seat for the person or persons riding in the carriage or cab is situated at the front of the body and over and parallel to the axle. The person riding in the carriage or cab are thus made to face the door at the back of the cab, the horse being concealed from view.—Patent completed.

3455 W. Burgess, Upton-on-Severn. Signal apparatus. Dated November 13, 1863.

ated November 13, 1863.

It consists of a barrel or tube provided with two projecting lugs, which slide on a vertical rod, rising from the centre of a base plate suitably fixed. An elbow plece projects from the vertical rod at its upper part, forming a fulcrum for a lever or trigger. One end of this trigger takes under the upper projecting arm of the sliding tube, and supports the latter in position, near the upper end of the vertical rod, by the end of a counter balance weight sliding on the other end of the said trigger. At the base of the tube is a nipple communicating with the interior on which is placed a precussion cap, the whole being closed by a conical or other shaped cap or cover, provided with a central pln or striker for acting on the percussion cap which ignites the charge contained in the tube,—Patent abandoned. bandoned.

3456 A. J. DEBLON, Fives-les-Lilles. Condensing rotary spine. Dated November 13, 1963.

3456 A. J. Deblon, Fives-les-Lilles. Condensing rotary engine. Dated November 13, 1963.

The rotary engine forming the subject of the present invention is expansive and condensing, and is characterized by the following features:—The steam cylinder is divided into a variable number of compartments, in which move a number of flyers or wings, which together form the piston of the machines. The employment of a hollow or drum cylinder, provided with steam escapes, and which receives motion from the driving that either by means of gear wheels, mounted on the said shaft, or any more convenient method. The erown of this cylinder is notched in as many places as there are wings to the piston, and corresponding with each of them.—Patent completed.

3457 O. JONES, Ealing. Treating sewage. Dated No-

3457 C. Jones, Ealing. Treating sewage. Dated November 13, 1863.
This consists in effecting the precipitation or deodorization of sewage, by the use of slaked lime, combined or mixed with hydrocarbons, such, for example, as petroleum or with the acid tar or residual product obtained in the treatment of ters, for and in the production of oils or other liquid hydrocarbons. Such mixture or compound is introduced into the sewage, just before it falls into a depositing tank. By this means, results are obtained as thoroughly satisfactory as by the more expensive salts hitherto used.

—Patent completed.

3458 W. N. NICHOLSON, Newark. Hay making machines.

3458 W. N. NIGHOLSON, Newark. Hay making machines. Dated November 14, 1868.

This refers to a pitent, dated July 6, 1954. No. 1485. The inventor now uses an intermediate or carrier pinion, which can be brought into gear with the pinion on the fork barrel, and with either the internal or the spur whoel at pleasure. When not required, he withdraws this carrier pinion, so that the sam simplicity is substantially retained, which is the characteristic of a former patent. In the nave of each travelling wheel he places two internal cog wheels, one smaller than the other. On the axie of the machine he mounts an eccentric cylinder, on which the fork barrels revolve, and by moving this eccentric cylinder round the axie he adjusts the position of the pinions on the fork barrels, so that they will gear with either of the two internal wheels.—Patent abandoned.

3459 J. B. GREEN, Bury. Size. Dated November 14,

or contract, so as to let the bearers take a firm position on the ground without throwing undue strain on the connection.—Patent completed.

3451 C. Markham and W. Knighton, Chesterfield.

Mowdling pipes. Dated November 13, 1868.
This consists in using talcum of that particular quality known as fine Fronth chilk, mixed with the size, as a substitute for tallow or sosp. After the flour mixture is made in the usual way for sizeing purposes, it is conveyed into a cistern to be boiled. When at boiling point, the intended to be cast. This cylinder is fitted with two or more grooves, running parallel with the axes of the

3460 T. Mills, Plumstead. Steam generators. Dated Novumber 14, 1863.

The firebox is constructed of a boiler (preferably of the upright form), of a coil or coils, of tubes or tubing, enclosed in a case, the fire being contained within the said coil, the bottom of which coil is connected by a tube or tubes, brought down outside from the upper part of the boiler, at the lower end of which tube or tubes is fixed a self-acting valve, placed in a horizontal position, which allows the water to pass on into the coil, the expansion of which water, through coming in contact with the heated tubing, closes the valve after it has passed through it.—Patent abandoned.

3461 W. Harrison, Fenton, Brick Hins, Dated No.

Patent abandoned.

3461 W. Harrison, Fenton. Brick kilns. Dated Novomber 14, 1863.

The inventor constructs the oven or kiln in the form of a long tunnel, provided with a chimney or flue at or near one end. The floor of the oven or kiln is provided with a transway or rails, upon which travel waggons, which are made of sufficient strength to carry, say, 2,000 bricks each.

—Patent abandoned.

Patent abandoned.

3462 J. HILL. Kensington Park Gardens. Preparing telegraph slips. Dated November 14, 1868.

The inventor arranges side by side a sufficient number of punches to produce all the varieties of letters or symbols required. These punches are acted upon by a lever through the intervention of a series of perforated plates constructed on the jacquard principle in such a manner that by bringing a certain plate between the lever and the punches only, those of the latter are acted upon so as to perforate the paper which represent the letter or symbol required, a fixed stop preventing the lever from moving further than is desired. The punches are, by preference, carried loosely by means of shoulders or notches in a plate actuated by a spring which withdraws them from the paper after the punching has been effected. The perforated plates may be actuated in various ways for bringing the required one between the lever and the punches.—

Patent completed.

3463 G. J. Worssam. Wenlock-road, N. Motive power.

Patent completed.

3463 G. J. Worssam. Wenlock-road, N. Motive power. Dated November 14, 1868.

The inventor avails himself of the property of bodies or objects of a certain specific gravity when immersed in a fluid of a greater specific gravity to rise or ascend to the surface of such fluid. He constructs these bodies of thin sheet metal, and preferably in the form of tubes or hollow cylinders with conical or flat ends. A number or series of these cylinders are hinged or linked together in a similar manner as the buckets of a chain pump. This chain of floats is passed over two sets of pulleys, discs, or arms, fixed to two horizontal shafts, the one placed vertically above the other, the said pulleys being formed to suit the shape of the floats. One half of this chain of floats passes through the centre of the tank holding the water or other fluid, and the other half passes outside the tank through the air. The floats, when in motion, enter through the bottom of the tank in the manner hereinafter described, and rise up by their buoyancy through the water; they then pass round the top pulley, descend outside the tank, and, passing over the bottom pulley again, enter into the tank, and so on.—Patent abandoned.

3464 R. Bechler and J. J. Hiors, Hatton-garden, W.C.

and, passing over the bottom pulley again, enter into the tank, and so on.—Patent abandoned.

3464 R. Becher and J. J. Hiors, Hatton-garden, W.C. Measuring flow of liquids. Dated November 14, 1863.

For a rain gauge the inventors employ appearatus constructed in the following muner:—The rain is conveyed to a measuring chamber which is supported by a float working in a chamber having a suitable quantity of quick-silver therein. Through the bottom of the measuring chamber is passed the longer leg of a syphon, the shorter leg of which nearly touches the bottom, whilst the bend of the syphon is coincident with the top of the measuring chamber, and is contracted so as to ensure the rain passing away from the measuring chamber by the longer leg of the syphon at a practically uniform level. The measuring chamber rises and falls according to the quantity of rain it contains, and is guided in its motion so as to ensure its rising and falling in a vertical line and prevent its turning on its axis.—Patent completed.

3465 H. E. Newton, Chancery-lane. Propellingvessels, (A. communication). Date I November 14, 1363.

This consists in the employment of one, two, four, or any other practical number of circular discs or annular rims or wheels mounted obliquely, and in different directions, upon a shift, and connecte it ogether, either at their edges, or along common chords or diametrical lines. The angle which represents the obliquity of the discs or rings with relation to their supporting soult is preferred to be about 154eg, but may be varied should any other inclination be required.—Patent completed.

## APPLICATIONS FOR LETTERS PATEIT

1521 F. Watton, Old Hall Works, Wolverhampton, Stafford-shire. Improvements in coal vases.

1521 J. Woodward, Queen's Foundry, New Islington, Ancoats, Manchester. Improvements in gas and water meters.

meters.

1923 W. Benson, Allerwash House, Hexham, Northumberland. Improvements in treating or reducing ores.

1524 J. L. Clark, Westminster, and J. Brotherton, Wol-

verbampton. Staffordshire. Improvements in the manu-

of iron and steel tubes.

A. V. Newton, Chancery-lane. An improved mode of, and apparatus for, manufacturing paper-hang-

ings.

1528 E. C. Warburton, Exchange-buildings, Bristol. Improvements in apparatus for registering secret votes.
1527 F. Johnson and W. Hatchman, Little Love-lane. City. Improvements in umbrellas.
1528 W. Green, Garforth, near Leeds. A new mode or method of cleaning flower and garden pots, both internally and externally.
1529 W. Naylor, Mildmay Park, Middlesex. Improvements in railway brakes, and in apparatus connected therewith.

ments in railway brakes, and in apparatus connected therewith.

1530 J. H. Johnson, Lincoln's Inn-fields. Improvements in firearms, and in apparatus for filling the same.

1531 E. Taylor, Central Works, Market-street, Blackburn. Washing, wringing, mangling, churning, and agitating liquids.

1532 H. Livesey, Greenbank, Blackburn, and T. Collison, Blackburn. Improvements in velocipedes.

1533 J. Sawyer and J. Woodman, Islington, Middlesex. Improvements in the mode of, and in apparatus for, the propulsion of velocipedes and other vehicles.

1534 R. E. Keen, Red Lion-court, Fleet-street, City. An improved mode of, and means for, securing panes of glass, more especially designed for street lamps or lanterns.

glass, more especially uses and terns.

1035 A. V. Winkle, Southampton-street, Bloomsbury, Middlesex. An improved device for securing corks in

Middlesex. An improved device bottles.

1536 W. R. Lake, Southampton-buildings, Chancerylane. Improvements in machines for manufacturing capsules for closing bottles, jars, and other vessels.

Dated May 19, 1869.

1537 E. H. and A. I. Solly, J. F. Hall, and R. Bailey, Congleton, Chester. An improved method of spinning or twisting two or more ends of yarn and simultaneously twisting the same into one thread.

1538 W. Martin, Manchester. Improvements in perambulators.

bulators.

1539 W. B. Lake, Southampton-buildings, Chancerylane. An improved process for obtaining gelatine and other products from animal substances.

1540 G. Martin, Lower Mills, Dursley, Gloucestershire. Improvements in the means of generating gases and chemical vapours employed in the manufacture of extract wool, and in destroying the vegetable material in mixed fabrics, and in the construction and arrangement of apparatus therefor, which apparatus is also applicable to other nurposes.

ratus therefor, which apparatus is also applicable to other purposes.

1541 P. M'Gregor, Falcon Works, Manchester, Improvements in machinery for spinning and doubling.

1542 J. T. Lucas, Brecknock-road, Camden-road, Middlesex. Improved velocipedes.

1543 J. E. and A. Dowson, Victoria-street, Westminster, Improvements in the construction of foundations for piers, bridges, and such like structures.

1544 A. W. Banks, Newgato-street, City. Improvements in velocipedes and other like vehicles.

1545 W. Mitchell, Waterfoot, Lancashire. Improvenents in the manufacture of felted cloth, and in the machinery or apparatus employed in such manufacture.

1546 D. Roberge, New York, U.S.A. An improvement in those for horses and other animals.

1547 G. V. Fosbery, Cowley, Middlesex. Improvement in procedular in the machinery of the machinery of the manufacture.

2521 G. V. Fosbery, Cowley, Middlesex. Improvement in the machinery of the manufacture.

1546 D. Roberge, New York, U.S.A. An improvement in the machinery of the manufacture.

1547 G. V. Fosbery, Cowley, Middlesex. Improvement in the machinery of the manufacture.

1548 D. Roberge of the manufacture.

1549 G. V. Fosbery, Cowley, Middlesex. Improvement in the machinery of the manufacture.

1549 G. V. Fosbery, Cowley, Middlesex. Improvement in the machinery of the manufacture.

1549 G. V. Fosbery, Cowley, Middlesex. Improvement in the machinery of the manufacture.

1543 F. Zysel and O. Burdett, Birmingham. Certain

1544 F. Zysel and O. Burdett, Birmingham. Certain impresements in velocipedes.

15'9 W. M'Adam, Glasgow. Improvements in the mar ufacture of pottery, and in the machinery or apparats a employed therefor.

1550 W. M. Moore, Balscaddin, Howth, Dublin. Improvements in caps or covers for the tops of bottles and other like receptacles.

1551 J. Langham, Leicester. Improvements in ash pans for firegrates.

1552 W. F. Fuller, Bank, Worthing, Sussex. Improvements in apparatus for securing or fastening the doors of

ments in apparatus for securing or fastening the doors of safes and strong rooms.

1553 J. Bowman, Peasholme Green, York. Improvements in fittings for window blinds.

1554 A. J. Dudgeon, Millwall, Middlesex. Improvements in propelling vessels by means of water.

1555 A. L. M'Gavin, Barge-yard, Bucklersbury, E.C. Improvements in propelling and manœuvring vessels, and in the apparatus employed for such purposes.

1556 A. L. M'Gavin, Barge-yard, Bucklersbury, E.C. Improvements in constructing and propelling ships and other vessels.

Dated May 20, 1869. 1557 Z. E. Coffin, Newton Center, Massachusetts, U.S.A.

Improvements in stop cocks or valves.

1558 C. C. Parker, Brooklyn, New York, U.S.A. An
improvement in cord tighteners for curtain fixtures.

1559 G. Perkin, Durby. An improved cup-and-ball G. Perkin, Derby. An improved cup-and-ball

castor.
1560 A. A. Rossignolf, Rue de Villiers, Paris. Cer
improvements in electric clocks.

1560 A. A. Rossignolf, Rue de Villiers, Paris. Certain improvements in electric clocks.
1561 J. Reid, Glasgow. Improvements in communicating between passengers and persons in charge of railway trains, and in appearatus employed therefor.
1562 J. M.Millan, Dumbarton, North Britain, and J. M'Gregor, Glasgow. Improvements in the preservation of iron and steel, and structures composed thereof.
1563 M. Jarvis, Mansell-street, Goodman's Fields, Middlesex, and E. Millward, Northern-buildings, Skinnerstreet, Somers Town, Middlesex. Improvement in lock spindles and door knobs to be used therewith.
1564 T. Herbert and J. C. Fowler, Riverhall-street, Surrey. Improvements in means for conducting electricity for communicating or transmitting signals and alarms.

1565 H. E. Newton, Chancery-lane. An improved portmill

able coffee mill.

1568 J. P. Nolan, Royal Artillery Barracks, Shoeburyness, Essex. Improvements in apparatus for measuring distances, particularly applicable to warlike purposes.

1567 W. B. Lake, Southampton-buildings, Chancerylane. Improvements in boat-detaching apparatus.

1568 G. Johnston, San Francisco, California, U.S.A. Improvements in the distillation of spirituous liquors, and in apparatus to be employed therefor.

Dated May 21, 1869.

1569 J. G. Tongue, Southampton-buildings, Chancerylane. Improvements in machinery for cutting wood or other substances.

1570 S. Jackson, Bradford, Yorkshire, Improvements 1571 E. H. Pulbrook, Tooting, Surrey. Improvements

organs.

1572 W. H. Dupre, Jersey. Improved apparatus for ving light and ventilation to rooms, houses, or other giving light and

giving light and ventilation to rooms, nouses, or outer-buildings.

1573 A. Munro, Arbroath, Forfarshire, and W. B. Adam-son, Glasgow. Improvements in treating certain metallic substances and certain metallic articles.

1574 J. Platt, Birmingham. Improvements in the manufacture of brooms and brushes.

1575 C. W. Siemens, Great George-street, Westminster. Improvements in calcining and smelting ores, and in furnaces and apparatus employed in connection there-with, which furnaces are also applicable to other pur-noses.

poses.

1576 A. M. Clark, Chancery-lane. Improvements in apparatus for facilitating the opening of eggs.

1577 W. R. Lake, Southampton-buildings, Chancery-lane. An improved machine for shearing, punching, bending, and otherwise working metal and metallic

articles.
1578 C. J. Forster, Maldon, Essex. Improvements in obtaining the transverse reciprocating motions of the cutter bar in resping, mowing, and other similar agricultural machines, and improvements in whoels for agricultural machines, which last-named improvements are also explicitly to reputing naming mytholes.

tural machines, which last-named improvements are also applicable to traction engine wheels.

1579 N. Lawrence, Great Prescott-atreet, Goodman's Fields, Middlesex. Improvements in lighting cigars.

1580 J. Hudson and C. Catlow, Burnley, Lancashire. Improvements in looms for weaving.

1581 W. Morris, South Hackney, Middlesex. Improvements in connecting and securing together the rails of railways.

railways.

railways.

Dated May 22, 1869.

1582 H. R. Lumley, Marlborough-place, St. John's Wood. Improvements in treating and purifying crude iron, and in making steel, and in an apparatus for such OSS. R. Orley, Axminster, Devonshire. Improvements

1833 K. Orley, Axminster, Devonshire. Improvements in invalid bedsteads.

1834 J. Lockwood, Leeds. Improvements in couplings for railway engines, carriages, and waggons.

1835 E. T. Hughes, Chancery-lane. Improvements in horse-shoe nails, and in machinery for the manufacture of

1885 E. T. Hughes, Chancery-lane. Improvements in horse-shoe nails, and in machinery for the manufacture of the same.

1886 G. T. Bousfield, Loughborough Park, Brixton, Surrey. Improvements in machinery for casting iron.

1887 J. H. Davis, Fenchurch-street, City. Improvements in ships' compasses.

1888 M. Tildesley, Willenhall, Staffordshire. Improvements in the manufacture of sash pulleys.

1889 S. Thomas, jun., Redditch, Worcestershire. Improvements in envelopes or wrappers for needles.

1890 W. H. Bliss, Bayswater, Middlesex. Improvements in the arrangement and construction of velocipedes.

1891 L. J. Crossley and R. Hanson, Halifax. Improvements in steaming yarns, and in apparatus employed therein, part of which improvements are also applicable for regulating the pressure of steam and other fluids.

1892 W. Furness, New-street, Borough-road, Surrey. A new or improved clip or fastening for uniting the ends or other parts of driving belts or bands, applicable also to braces and other useful purposes.

1893 W. Mitchell, Manchester. Certain improvements in the method or process of grinding metallic articles, and in the mechanism connected therewith.

1894 B. F. Weatherdon, Chancery-lane. An improved reacting turbine wheel.

1895 W. A. Gilbee, South-street, Finsbury, Middlesex. Improvements in ice houses, store rooms, and refrigerators.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sont, payable to Robersson, Brooman, and Co., Patent Department, 166, Fleet-street, London, E.O., to whom all communications upon the subject should be addressed.

Science and Art .- A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the the great power of skilled mechanical labour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brooches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to and they cannot be too strongly recommended to those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[ADVI.]

#### **MECHANICS'** MAGAZINE.

LONDON: FRIDAY, JUNE 4, 1869.

# PROPOSED ABOLITION OF PATENT

THE name of Sir William Armstrong has become immortalized in the annals of the British Association by two things chiefly. Upon one occasion, he startled the world by the announcement of the probable and imminent exhaustion of our coal fields, and at another time—in 1862—he made a furious onslaught upon the principle of our patent laws. Sir William's point of attack was, as might be expected, that of a manufacturer who had an idea which he wished to work out, but could not do it because another man's patent stood in his way. Of course, it was open to him to buy the invention at a stated price, but this was neither so convenient nor so economical as getting the Legislature to sweep away all protection from inventors, so as to be able to adopt their plans without let or hindrance. In a word, the necessity of buying inventions which he wished to adopt, hampered the manufacturer, and, in his eyes—as well as in the eyes of the supporters of free trade in other people's ingenuity—this objection was fatal to the whole patent system. This took fatal to the whole patent system. This took place just seven years ago, and a considerable stir was created at the time. Since then, however, matters have been quiet in this direction, with the exception of an occasional agitation for reform, which, in some respects, is really needed. Recently, however, another specious attempt to appropriate the work of other men's brains has been made in another and more important quarter. We need hardly say we refer to Mr. Macfie's recent motion in the House of Commons. Last Friday evening, that gentleman moved a resolution to the effect that the time had arrived when the interests of trade and commerce, and the progress of the arts and sciences, would be promoted by the abolition of patents for inventions. The motion was seconded by Sir R. Palmer, who held that arts and manufactures in this country had attained such a point that props of this artificial nature might be well dispensed with. As might naturally be expected, a long and animated discussion ensued, and, as might also naturally be expected, it ended in a withdrawal of the motion. The Attorney-General who knows something of the working of the patent laws, very justly condemned the resolution as a dangerous experiment, and one which ought not to be made without full and searching inquiry. There were, he observed, no doubt, evils in the working of the present system; but these could be remedied, and the Legislature should certainly try to amend and improve before abolishing. One recommendation of the Royal Commissioners would certainly be a great improvement. He alluded to the trial of patent cases by a judge, with one or two scientific men as assessors, instead of by a jury. He believed that the working classes, as a body, were opposed to the abolition of the patent laws.

Now, it so happens-as in Sir William Armstrong's case—that Mr. Macfie is a manufacturer, one of the only class which would benefit even temporarily by the abolition of the patent laws. But for the credit of that class, we can point to another member, who—to his honour be it recorded—stood boldly up for the rights of the inventor, generously repudiating Mr. Macfie's unjust proposal. This was Mr. Mundella, whose opening remarks were as follows:—He wished the House to was Mr. Mundella, whose opening remarks were as follows:—He wished the House to consider what would happen if the patent laws were abolished. He had been for twenty-five years connected with manufactures as an mind as we write which would overwhelm

employer, and during that time, he might say, he had more than twenty patents, in every one of which he had a working man in partnership with him. He had never made an invention in his life; he did not know in his neighbourhood of one invention made by an employer. Inventions were generally made by working men; and a working man now received from his hon. friend, the member for Bristol, and himself, a third share of the profits of a patent invention, which produced to him a very considerable sum annually. He had himself gone into a garret, where he found a poor man working on a circular re-volving machine, which he had fixed on the bottom of a wooden chair—the only chair in the room. For years he had been patiently working at it. It was completed. It was patented. He purchased it. The poor man had his share, and was now in comfort and independence. No parties had a greater interest in the maintenance of the patent laws than working men, who if they received no protection here for their inventions, would soon carry them off to France or America. Such was the tenour of Mr. Mundella's speech, which, to the end, was plain, outspoken, and honest, and will assure the poor inventor that he has at least one friend to stand by him in the Houseone who could and would carry matters much farther if the hour of need came. Nor does Mr. Mundella stand alone. With him also we are proud to associate Mr. John Howard, of Bedford, whose experience has taught him the value of patented inventions, and whose honesty of purpose showed itself in his re-marks in the House upon the present question. The threatened danger, however, is for the present averted, and Mr. Macfie, satisfied-or more probably dissatisfied—with having elicited a discussion, withdrew his motion. Here, then, the matter rests, and Mr. Macfie has earned for himself the unenviable distinction of having proposed the abolition of the only protection at present possessed by the great mass of our meritorious inventors.

We must certainly confess to not having been over anxions as to the issue of the event in the House of Commons. We felt event in the House of Commons. assured that the present Government, with all their desire to abolish existing institutions, and to reverse many of the decisions of their predecessors, would not succeed in breaking down the barriers of the British inventor's stronghold. The motion has broken down on the threshold. But although this is the case, we cannot let the present opportunity pass without a few words more upon the patent law. The recent attack upon it justifies our remarks, which we know will be echoed by every one of our readers. We would ask all rash intruders upon the rights of the inventor if it is nothing that the patent system has attained to dignity by age and prescription? But, above and beyond all this, is its utility and very fitness to the social condition of nations. At home, abroad, wherever civilization has impressed its stamp. there the patent system is adopted with manifest advantage. What of its prosperity does not our own land owe to this system? Our colonies and dependencies recognize the fact that the patent system underlies the successful development of their commercial interests, and they adopt it. Everywhere public and private enterprise bear incontrovertible testimony to its efficacy, whilst our national commercial standard has unquestionably been elevated by its agency. These are a few of the considerations we would submit to those who, like Mr. Macfie, consider that "the interests of trade and commerce, and the progress of the arts and sciences, would be promoted by the abolition of patents for inventions," as well as to those who, like Sir R. Palmer, think that "the arts and manufactures in this country have attained such a

every argument advanced in support of so mischievous a proposition, but we find them so fully and forcibly set forth in a recent able article upon the subject in the "Standard. that we gladly reproduce that article on another page. It is enough for us that we have witnessed the prompt and decisive defeat of a proposal which struck deeply at the root of our national prosperity. It is enough that the end followed so immediately upon the beginning. It is enough that we have such plain outspoken men as Mr. Mundella amongst us to expose those who seek private aggrandisement under the pretext of public good, and who seek to elevate prejudice into principle. We ask men of all classes to pause before they listen to idle and meaningless clamour, and before meddling with a system by which private firms and public companies have attained affluence, by which also work is provided for many hands, and public wealth and comfort are increased. Let none commit themselves rashly to a course of action inimical to the best interests of the State, because dull and idle persons are precluded from availing themselves of the brains of brighter men. England would have cause enough to regret if she were to refuse justice to the inventor, and, in being unjust to him, were unjust to the millions whom his skill and genius enrich and benefit.

## LAYING CULVERTS UNDER THE BEDS OF RIVERS AND CANALS.

HERE is always more or less hazard and risk in disturbing what may be called existing state of things." Nevertheless, it becomes imperatively necessary, on certain occasions, to incur the risk of so doing. Of all the examples of engineering practice, in which a corroboration of this statement is to be found, that relating to interfering with the status quo of the beds and banks of rivers and canals affords the most conclusive one. Numerous have been the accidents, and dire the consequences of excavating even in the approximate locality of these situations. It is impossible to observe too much caution in conducting operations of this nature, which have now become more frequent than formerly. This is partly owing to the fact that rivers are no longer regarded as inseparable barriers between their opposite shores, and that attention has, during the last few years, been prominently drawn to the practicability of effecting a communication underneath instead of overhead. This has been exemplified on a gigantic scale by the proposed submarine communication between England and France, and is being practically carried out by the Waterloo and Whitehall Pneumatic Company, and by the construction of the subway under the Thames at the Tower. Although not arrived at this pitch of subfluvial tunnelling, the French have accomplished something in that line, by the large syphon tube recently successfully laid under the Seine, to connect the sewage channels on each side of that river. The laying of culverts and pipes under embankments has always been a source of anxiety and trouble to the engineer, even when the embankments are made at the same time. It is needless to point out how greatly the trouble increases, and how much greater need there is of precautionary measures, when the case involves the undermining of a bank already in situ.

There are two very prominent instances to be adduced where the laying of pipes and culverts underneath the banks of water reservoirs were attended with leakage and bursting. The one is the well-known catastrophe at Bradfield, some few years ago. The other is the leakage and subsequent emptying of the

working defects, there is very little doubt about the latter. The extrados of the arch of the culvert was left nearly smooth, without any offsets, steps, or "racking back," afford a firm hold of the puddle of the bank. In fact, there was really a straight joint between the puddle and the masonry, whereas there should have been a union as intimate as it was possible for ingenuity to imagine. As might be expected, the water found out the "weak spot." The result was the emptying of the reservoir, which had taken months to fill, and the plunging of the Dublin Corporation into litigation, which entailed upon it a large amount of expense. In many of the towns where new sewage works are in course of construction, it has been necessary to lay iron pipes below the beds of the adjoining rivers and canals, both for the purpose of effecting a communication between the sewers upon the opposite sides, and also, in some instances, to constitute a channel of conveyance for the sewage to the fields intended to be irrigated. This subaqueous plan has been adopted at Norwich, where very extensive drainage and sewage works are in progress. Some idea of their extent may be gained from the fact that they are estimated to cost £60,000. Provided the foundation he good, and concrete be used liberally, the only point presenting much difficulty is the joints, which sometimes give a great deal of trouble.

The depth to which the drains must be sunk depend, in the first place, upon the levels; and, secondly, upon the condition of traffic in which the river is placed. If the river be navigable, and used for the purposes of navigation, the pipes should not be placed too near the surface, and should be well protected, especially about the joints, with cement concrete, or they are liable to be damaged by the anchors of boats. Were there any choice in the matter, it would always be preferable to take the drain or pipe over instead of under the river, but it is seldom that the levels are so entirely optional as to afford the right of

An instance of the bursting of a canal embankment, in consequence of excavating underneath it, for the purpose of constructing a culvert, occurred a very short time ago. It appears that a portion of the embankment of the Napton and Warwick Canal, on the Warwick side of the river, was washed away, The breach made was nearly 40ft. in width, and the water escaping through it with great velocity completely inundated the adjoining fields, and did a great deal of mischief to the young crops and property. Although the conclusion is not absolutely an infallible one, that the proposed construction of the sewer was the cause of the accident, yet, when it is borne in mind that the excavation was carried on in close proximity to the breach, it is difficult to trace the effect to any other cause. As a rule, we should prefer in these hazardous situations to lay cast-iron pipes instead of building a culvert. The time which the disturbance and interference with the existing bank occupies is of equal importance with the nature of the operations carried on. A much shorter time will suffice to lay in a pipe than to construct a culvert of brickwork or masonry. The former will also require less excavation than the latter, for supposing them to have the same internal dimensions, the arch, invert, and side walls of the culvert, will necessitate the taking out of a considerable additional quantity of earth. These proportions in a cast-iron pipe are simply its thickness, which practically is inappreciable. Besides, an increase in the capacity or internal size of the pipe, produces little or no corresponding difference in the thickness. With the exception of the difficulty sometimes experienced in making good the joints, there is no comparison with respect to the relative facilities of the two methods for establishing a speedy and secure communication between the opposite banks. The manner in which the canal is constructed, at the ing the special attention it deserves, was a

place where the intended pipe or culvert is to cross, has a very great effect upon the risk attending its successful laying. Should the canal be carried altogether in an embank-ment, and the levels not permit of the pipe being laid in the natural ground, but require it to be placed in the artificial bank, the danger is seriously augmented. Not only is the foundation more treacherous and insecure, but the earth above is more liable to subside than if it consisted of a thin stratum of the natural surface. Subsidence is not necessarily a forerunner of leakage or bursting, but it frequently does precede those serious contingencies, and may be regarded as a warning sign which should never be disregarded. A distinction must be drawn here between the ordinary subsidence, which invariably follows the erection of every new bank, a short time after its construction, and that for which there is no apparent cause. The former is always expected, and provision made accordingly for raising the bank to its proper level. The latter should be at once carefully inquired into, and a constant watch set on the spot.

# CONVERSAZIONE AT THE INSTITU-TION OF CIVIL ENGINEERS.

N resuming our notice of the exhibits at the recent conversazione in Great Georgestreet, we will first refer to the very ingenious method devised by Mr. S. P. Bidder, jun., for locking miners' safety lamps. On the bottom being screwed on, a bolt is pressed upwards into a recess by a spring, and can only be withdrawn by means of a powerful electro-magnet, which is to be kept in the lamp room. This entirely dispenses with the lock and loose keys. Mr. Bidder also exhibited a model of a machine for breaking down coal without the use of gunpowder, which illustrated a system possessing great merit. next thing we shall notice is one of Harrison's synchronous clocks, before describing which we may premise that one of the projects in the formation of the London District Telegraph Company was the diffusion of Greenwich time by telegraph throughout the City and the suburbs. The Astronomer Royal offered every facility for obtaining either hourly or—if desired—minute currents from the Royal Observatory. It then remained that the translation of sleek health as a content of the co that some kind of clock should be constructed which would record the precise moment at which the hourly current was received. Many attempts were made by which a delicate regulator could be set for five seconds of error either fast or slow. The clock exhibited by Mr. Harrison will correct itself for any degree of error, whether fast or slow, on the receipt of a feeble current of electricity. Mr. Harrison seems to have made himself acquainted with the difficulties which surrounded the setting mechanism, and has, in a simple manner, shown that, submitted to the severest tests, a clock of the most ordinary construction can be corrected and made to show the true time by a very simple process of electrical setting. The setting of the synchronous clock is performed by the clock itself on receipt of a current of electricity for any degree of error in hours, minutes, or seconds, whether fast or slow. No electrical break in a line of clocks, however distant or numerous, is required. Residuary magnetism is impossible, the armature being raised 90deg. from the coils, until it is placed, after an interval of thirty minutes, in position by the setting apparatus. For all purposes where correct time is required, such a clock must be invaluable. For some time past, the Astronomer Royal, Mr. Ellis, Mr. Denison, and others, have been urging the construction of such a clock as the one so successfully designed by Mr. Harrison.

working model of Mr. Hodgson's wire rope transport system. This invention, which was described by us in the early part of the present year, has now been carried out in various places, the successful results of its working at the Bandon Hill quarries having stamped it as a practical invention. main object is the construction of light and cheap ways for the transport of mineral or agricultural produce in localities as yet un-provided with railways. The system may briefly be defined as a continuous development of the plan now not unusual in India, Australia, and in some mining districts, of bridging over a river or ravine by a single wire rope, by which the loads are carried in a bucket suspended by a pulley, and are thus transmitted from one point to another. The importance of this invention in connection with the transport of minerals justifies here a farther reference to the details of the system. To accomplish the easy passing of the points of support necessary to carry out a continuous line of communication, and to provide for the distribution of the and the application of motive power, have been problems of no small difficulty. After experiments on a first trial length of half-amile, during the autumn of last year, these practical details were worked out, and a line of three miles in length, near Leicester, has recently been completed. This wire consists of an endless wire rope, supported on a series of pulleys carried by substantial posts, which are ordinarily about 150ft. apart, but, where necessary, much longer spans are taken, in one case amounting to nearly 600ft. rope passes at one of its ends round a Fowler's clip drum, worked by an ordinary portable steam engine, and the rope is thus driven at a speed of from four to six miles an hour. The boxes in which the stone is carried are hung on to the rope at the loading end, the attachment consisting of a pendant of peculiar shape, which maintains the load in per-fect equilibrium, and, at the same time, enables it to pass the supporting pulleys with ease. Each of these boxes carries 1cwt. of stone, and the delivery is at the rate of about 200 boxes or 10 tons per hour for the threemile distance. In the case of lines for heavy traffic, where a series of loads, necessarily not less than 5cwt. to 10cwt. each, must be carried, a pair of stationary supporting ropes, with an endless running rope for the motive power, will be employed, but the method of supporting, and the peculiar advantage of crossing almost any nature of country with a goods line without much more engineering work than is necessary for fixing an electric telegraph, without bridges, without embankments, and without masonry, exists equally in both branches of the system. The model admirably illustrated the system and its value as affording a cheap and continuous line of communication.

In railway matters, we have models of Mr. Price Williams' railway switches and crossings. The leading features of Mr. Williams' switch are as follows:-When the main line is open, and the switch is closed against the siding, there are no facing points. This alone would suffice to show the value of the invention to all who have the care of the traffic on through lines of railway, where the danger of facing points is so manifest. To do away of facing points is so manifest. To do away with this danger is the main object of the invention. By means of an ingenious arrangement of sliding fish plates, the switch rails are fished up in every position, whether they are set for the main line or the siding. This arrangement ensures the accurate fit of the rails, and renders any shifting almost impossible. The switch is twisted into place. i.e., the joints about which the two rails of the switch turn are at opposite ends of the switch. The rails are all butt-jointed, and there are no tapered points. Thus the durability of the switch is provided for. It will thus be seen that for shifting the switch, three separate operations are necessary -first,

the rails must be unfished; next, the switch rails must be thrown over into position; and, thirdly, the rails must be fished up again in their new position. All this is done at one lever in the most complete manner by a very simple arrangement of rods and bell cranks. A short semaphore signal, similar to an ordinary facing point signal, is worked by the switch lever, and indicates that all is in proper adjustment. Had Mr. Williams confined himself to what is strictly necessary for working the switch, a gap would be left in the main line when the switch is set for the siding. Thus an engine or truck on the main line might, through carelessness or accident, run off the line at this gap. To meet this difficulty, a simple addition to the switch, in the shape of two short inclined pieces of rail, has been made. Any truck on the main line will then mount upon the switch rails by means of the short inclined pieces, and pass over them, as in a "drop crossing," such as is sometimes used in temporary tramroads. Thus the truck remains on the line, and no accident occurs. It must be remembered that the above arrangement can only come into play in the event of some negligence on the part of the pointsman, and is an indication of the care which the inventor has used in providing for all possible contingencies. Mr. Williams' crossings will be found described and illus-

trated on another page.

We next come to a working model of Mr. Charles Lea's gates for level crossings. model exhibited a recently patented improvement of an apparatus—originally patented some years ago by Mr. Lea—for the safe working of gates at railway crossings. The gates can be opened by the movement of a hand lever, which is connected with distance signals, and also with signals adjoining the crossing. By throwing the lever over, danger signals are raised, the gates unlocked and closed across the railway. The reverse operation frees the line and again locks the gates upon the high road. As it is impossible for the gates to be opened without the signals being simultaneously raised, and as the latter cannot be released until the gates are again closed and locked, perfect safety is ensured at the crossing. We are informed that gates upon this principle have been adopted on crossings on the London and North-Western Railway and on the Midland and other railways. Rapier exhibited a wrought-iron signal post, 70ft. high, as arranged when packed for transport. It occupies but a small space, being only about 12ft. in length by 10in. across. In this structure, iron tubes are used in groups of three, and are connected together by cast-iron triangular pieces. were various models of improvements in permanent way, by Mr. Ashcroft, Mr. Gregory, and Mr. Livesey. Mr. Rapier also exhibited models of his continuous railway crossings, with Mr. Price Williams' grooved rail applied to them. One system illustrated was that applicable to roads laid with cast-iron sleepers, the other being adapted to our home lines. Mr. E. Barnes sent an illustra-tion of a method proposed by him for coupling the vertical and horizontal wheels of locomotives used on the Mont Cenis Railway. He constructs the engines with outside cylinders, and places between the two axles, and some-what above the level of the latter, a cross shaft, provided at its ends with cranks, which are coupled by rods to the cranks of one of the pairs of vertical wheels. From this cross shaft the vertical shafts carrying the horizontal gripping wheels are driven by means of spiral gearing, the pair of horizontal wheels on each side of the mid rail being coupled by cranks and coupling rods. Mr. A. Alexander exhibited a model of another arrangement of locomotive for working a mid rail line. In this plan, the centre rail is gripped laterally between the peripheries of several pairs of vertical wheels carried by

engine. The cross shafts are coupled in the ordinary manner to the axles of the carrying wheels. Mr. T. Claxton Fidler sent a model of his articulated rolling stock, in which the axles are all truly radiated to the curve traversed, whatever its radius. The carriage has a pair of independent frames carried on three pairs of wheels, the arrangement being exceedingly well adapted for very sharp

Mr. R. F. Fairlie sent a model of his steam train bogie carriage, for working light and branch railways, or limited express trains on main lines. A carriage on this principle is now in course of construction, and is to be worked on one of our metropolitan lines. We trust Mr. Fairlie will there have an opportunity of proving practically that economy of railway working of which he has been so untiring an advocate. Mr. Fairlie's system is also applicable to street tramways, the steam carriages being similarly constructed, except with regard to the arrangements for taking up and setting down passengers. The carriage for roads stops to take up passengers like an ordinary omnibus, and does not emit smoke or steam in the usual way, the smoke being consumed and the steam condensed. The carriage for light railways has compartments with side doors to open on platforms, similar to those at present in use. The following are the general leading particulars of Mr. Fairlie's steam carriage:—Cylinder, 8in. diameter; stroke, 12in.; coupled driving wheels, 4ft. diameter; steam pressure in boiler, 150lb.; effective pressure on pistons. 100lb. per square inch; tractive power, 1,600lb.; diameter of trading bogie wheels, 30in.; extreme wheel base, 57ft.; clear width of carriage inside, 8ft.; total weight of steam carriage, with fuel and water for a 40 miles' run, 14 tons; accommodation for 90 passengers, weighing 6 tons. The steam carriage has ample power to take one additional light carriage, specially constructed to accominodate 100 passengers, or two light carriages with 50 passengers in each, at an average speed of 30 miles per hour, up gradients not exceeding 1 in 60, and with a consumption of coke less than one-third of the ordinary passenger locomotives now in use. The maximum weight in the driving wheels is reduced to 21 tons per wheel, instead of 5 to 8 tons on a wheel, as now ordinarily in use, thus effecting great economy in the main-tenance of way and wear and tear of rails. From the extreme length of wheel base the steam carriage will be remarkably steady at high speeds, when running in the straight line; and by the arrangement of the double bogies can pass round curves of the smallest radii now in use with great precision and steadiness, and at the termini can be turned slowly on a semicircle of 60ft. in diameter. For the purpose of repairs, auxiliary or supplementary wheels are provided, which may be lowered on to the rails when the steam bogie is detached from the carriage, which can be done in a few minutes. The guard and engine driver are in close communication, and a platform with hand rail round the sides of the carriage, or, in the case of saloon carriages, a passage down the middle is provided to enable the former to communicate with the passengers when necessary This carriage while the train is in motion. is, in fact, a complete train in a condensed form. Its cost will be about one-third of an ordinary train of same capacity, while it possesses the important advantage of half the whole weight being made available for

adhesion on the rails or tractive power.

We next notice Mr. Scott's excellent wheel-moulding machine, which, during the past three years, has proved a great success. This success is attributable to the advantages embodied in the machine superseding the old system of moulding wheels from entire wood

thod, and to remedy existing defects by mechanical contrivance. He thus reduces the enormous expense of sustaining cog wheel plant to an ordinary trade outlay. This object is attained by the following means:— A trammel of any desired radius revolves around a central axis; at the end of the trammel is a vertical slide to hold the segment of a wheel, capable of being raised and lowered; a dividing apparatus moves the trammel the required distances on the circumference, the whole being portable. This combination secures a true periphery, the mould of the tooth and space perfect in finish, the accurate relative position of the teeth, together producing the best wheels with greater correctness and economy than by making patterns or cutting wheels by machinery. We next come upon Mr. De Bergue's hot air cooking stove, which is constructed upon scientific principles, so as to produce, from the combination of a large quantity of common air mixed with a small quantity of gas, a perfectly pure and rarefied hot air, which, it is stated, will cook steaks or chops in from seven to nine minutes, and other meats in a proportionate time.

We were much pleased with the models of Captain Saunders patent safety springs for anchors, chains, harbour moorings, and other similar purposes. They consist of a series of discs of metal and india-rubber placed alternately, as in a buffer. About five years since, when it was considered necessary to make it imperative that all ships' cables should be tested by submitting them to strains which impaired their strength for after service, Captain Saunders, a practical seaman, invented this cable safety spring to attach to cables in heavy riding, and which may be applied or removed at pleasure. Finding great difficulty in getting it tried practically by the Admiralty, and seeing it was from that quarter the merchant service looked for a report, Captain Saunders was induced to transmit his plans, with diagrams, to Calcutta, soon after the great cyclone of October, 1864, swept over that port. The harbour authorities called a committee on the subject, and it was resolved to try the springs. Accordingly, forty were ordered to be tried on the port moorings, and some of smaller size were purchased for their light and pilot vessels. These were duly reported upon as highly satisfactory, and orders are now annually given for the springs. We regret to learn, however, that only a few of our shipowners have adopted them. The reason for their indifference is the old one-"My ship is insured, and Lloyds' rules do not require any supplementary tackling to help the cables." In other words, "We don't care to prevent them breaking." Experiments were tried last year at Sheerness, and we understand that a favourable report was forwarded to the Admiralty. The only result, however, has been an intimation to the inventor that these admirable means of safety are not at present required for the Royal Navy. In many instances, however, these appliances have proved invaluable to those private owners who have adopted them, as numerous certificates testify. The combination of the buffer with the stopper, as arranged by Captain Saunders, is of the first importance, as the spring is in operation when anchoring the ship, in riding, and in weighing. We certainly think the attention weighing. We certainly think the attention of our naval authorities ought to be given to these means of safety, for when every ship carries a pair of these springs we shall undoubtedly hear far less of parted cables, stranded ships, and the attendant loss of life

and property.

Mr. W. Austin sent an example of his system for effecting verbal communication in railway trains between guards and drivers. It merely requires a whistle at each end of gripped laterally between the peripheries of several pairs of vertical wheels carried by cross shafts, placed between the axles of the

coupling is on the bayonet joint principle, and is a most ingenious contrivance. It can be easily and instantly attached or detached by the fingers. This apparatus can be used on board ship to convey messages down from the mast head to the deck, or any part of the ship. The great advantage here would be in getting a clear message to descend, especially when blowing hard at sea. We understand that the system has been tried on board the "Great Eastern," but has not yet come so prominently before the public as such an invention should. Messrs. R. and J. Beck sent some very interesting apparatus illustrative of the application of photography to meteorological purposes. These were the thermograph and the barograph, as adopted by the Kew Committee. The first of these is used for recording the thermometric, and the latter the barometric, changes, by means of photography. Messrs. Beck also exhibited Beckley's self-recording anemometer, which is the standard established by the Board of Trade for comparison with other instruments. As we hope in our next to give our readers full particulars of these beautiful instru-ments, we shall not further describe them here. There were also a number of inventions exhibited which we do not now stay to particularize, as some have recently been described and illustrated in our columns, whilst special notices of others will be found in our present and next numbers. Amongst the former, we may mention Mr. Outridge's equilibrium slide valve, which is at work on the Cowes and Newport Railway; Mr. Waters' feed-water heater, described by us on the 14th ult.; Captain Albini's self-registering compass; Mr. Allen Ransome's feed motion for wood-working machinery; Mr. Rogers projectile anchor and carriage; Mr. Sax's alphabet telegraphs; Mr. Wither's insubmersible lifeboat; Mr. Brinsmead's pianoforte repeater action, &c, &c., &c.
Mr. Whitworth exhibited cross sections of

his 9-inch gun and polygonal projectile, illustrative of his system of windage. He also had cross sections of a 9-inch gun and a studded projectile, showing the windage, the specialities of all of which were explained by Mr. Whitworth with that clearness which adds such value to all his statements. We must not forget to notice the beautiful models, lent by Messrs. Maudslay and Field, of their regular type of oscillating paddle engines, and of the engines of the "Agincourt," 1,350-horse power. Messrs. Miller and Ravenhill, and Messrs. Penn, sent not less beautiful models of the engines of the Irish mail boats, "Leinster" and "Connaught," and of the engines of H.M.S. "Northumberland" and "Minotaur." These gems of modelling art were kept in motion by an arrangement of shafting devised by Mr. Jabez James, and which was driven by the gas engine used for ventilating the hall and which gave a marked feature to the conversazione. Mr. James himself exhibited a model of a pumping engine, and an engine counter. Another attraction in the room was a letter stamper, designed by Mr. Pearson Hill, and in use at the General and provincial post offices. With this machine, an attendant effaced two hundred envelopes. per minute. The apparatus is highly ingenious, being self-inking, and so arranged as to enable the operator to work with ease as well as rapidity. It will stamp from two dies at the same time, one of which effaces the postage stamp whilst the other marks the date on the letter. Colonel Clarke, R.E., sept a model of Haulbowline Yard extension, a model of a caisson for the basin entrance at Haulbowline, and a model of the caisson for dock in French Creek at Malta. The details of this latter work were designed by Mr. W. T. Carrington, C.E. The caisson is 81ft. 6in. long above water line, 12ft. 4in. wide, and 38ft. high from bottom on sliding

in place, forms a roadway between the two sides of the dock entrance, and is strong enough to allow vehicles to pass over with a 10-ton load. The caisson is arranged to go into a camber when the dock entrance is required to be open, and this camber is bridged over for a length of 52ft. by strong wrought-iron girders and oak planking. This bridge or covering is permanent, so that there can be no interruption to the traffic along that side of the dock. When the caisson is in place, the level of its deck must be the same as the level of bridge over the camber; and, therefore, before moving the caisson into the camber, the deck has to be lowered 2ft., and the railing laid flat upon it before moving the caisson.

We have now taken our readers with us over the collection of interesting models, &c., which were presented to view at the last conversazione of the Institution of Civil Engineers. Of course, we do not pretend to have noticed everything; we have, however, made a selection of those matters which were most prominent, most novel, or of most interest to our readers. It only remains to us to acknowledge the courtesy of the president, the secretary, and other officers of the Institution, and to thank them for a pleasant and instructive evening.

## NOTES ON OUR NAVY.

BY a recent Admiralty order, I perceive that governors are at last to be introduced in all twin screw gunboats. Why the engines of light draft ships with a single screw should be allowed to remain without such a necessary adjunct is beyond my power to explain. I can only attribute it to one fact, viz., men in power have so long run on in the same old-fashioned groove that they will not see the immense advantages which such an improvement confers. In former years, the far-famed "Himalaya" was constantly breaking some important part of her machinery, or flinging her propeller off, but since the governor was put on I am not aware that a single accident has occurred, and the engineer informed me that he felt no anxiety now in the heaviest weather. Often when running before a heavy gale have I watched the engineer on duty standing by the throttle valve for hours vainly essaying to control the racing of the valuable machine under his charge. "She will tear herself to pieces" a common remark at such a time, and if any one will take the trouble to compare the difference in the cost of repairs between equally matched ships, one being fitted with a governor and the other not, he will find the engineer's remark perfectly correct.

Slowly and painfully is machinery making its way in the navy. The absurd idea still prevails that its introduction would leave the crew of a man-of-war nothing to do. It will indeed be a grand triumph of engineering skill when such a day arrives. But no man need fear that such a state of things would lessen the demand for human labour, although a higher degree of intelligence and education on the part of naval officers will be absolutely necessary in order to direct the management of such an elaborate machine as a highly finished ship will be. Let no man deem that the day of good seamanship has passed away. So far from this being the case, I am of opinion that the demand for it is more imperative than before. In the battles of the old war, blunders escaped with impunity which would now cause the loss of a ship. It is, therefore, absurd to hear men say that the engineer and stoker will fight our future actions on the ocean. In an old "Times," I have read the speech of his Grace of Somerset on the seagoing capabilities of these boasted American monitors (my views have been published long since). I find that he is

posed deck is only 1ft. from the water, and that such vessels are rather desirable places of residence for our seamen than otherwise. Such a remark reminds me of the recipe for feeding the poor which emanated from another noble duke some twenty years since. Where he gathered this information from I cannot imagine, for if he is really desirous of acquiring a correct account of their behaviour in a seaway, I would refer him to the journal of one of the officers, published in the "Nautical Magazine," who, when crossing the North Sea, describes the feelings of the English pilot as he watched the green seas rolling overhead on the thick glass decklights. No doubt such vessels would be serviceable as coast defences, but they must be built of much stronger materials, and on very different lines to what they are at present, or they would succumb to a blow from the iron stem of an ordinary ocean mail steamer.

It is a misfortune for England that so many of her great undertakings in ship-building should be decided by men who have no real knowledge of the principles on which a ship is built. For example, we take a venerable admiral from his snug London club, and give him command of a fleet of new ships. For years probably he has not been to sea at all, or troubled his head about the changes which science has wrought in the interim. Hence, the reports are so conflicting and contradictory about any particular type of ship, that builders are at a loss to guess what is required. No ship has ever been so much praised and condemned as the "Bellerophon," and the consequence is that "Bellerophon," and the consequence is that the public are ignorant of her true character; and I may add that professional men have gleaned nothing from the published accounts of her trials except a harvest of doubts. The same may be said of the Indian troopships.
The "Army and Navy Gazette" spoke constantly of their high rate of speed, their exemption from rolling, and general seaworthiness; while another naval paper flatly contradicted these statements, and described their rolling in terms more applicable to ironclads than ordinary ships. Of one thing, however, we are certain, and that is that their mean speed is painfully low, averaging from eight to ten miles an hour only, a rate which would ruin the reputation of any great

steamship company.

I see by the papers that Admiral Hornby is about to commission the so-called flying squadron. Where are they to fly to? and, when they reach their destination, what can wooden ships, armed principally with smoothbore light guns, effect, supposing that an imperative demand for their services arises. I know that the bill for caulking alone will amount to no mean sum. It is true that such a squadron would be able to dictate laws to the maritime provinces of the republication. the maritime provinces of the republics of South America, or the islands of the eastern seas; but we should not disguise the fact that complications of a grave nature are at our doors. Not long since, a member in the House of Commons said-"In the event of a war with a great naval power, our wooden ships must seek safety in flight." Yet, in the face of this danger, we increase the risk and send a large portion of our force beyond the reach of the telegraph. I believe, however, that the first cruize of the flying squadron will be its last; the country must, therefore, be prepared to pay for experience on such an important arm of its defence.

NOTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-PLICATIONS.

wide, and 38ft. high from bottom on sliding seen published long since). I find that he is of opinion that these ships are of the most dry upper deck or platform, when the caisson is and buoyant description, although their ex-

AFTER THEY WERE WRITTEN—THE BYE AFFECTIONS OF COMPOSITORS.

on M. Chasles as genuine, and which, if genuine, deprive Newton of the honour of all his great discoveries. That they are forgeries, and not very clever forgeries, few men of distinction, even in France, have any doubt, although the motive of the forger is obviously to give Pascal the credit of having made most of Newton's discoveries. Some letters, which it is pretended were written by Milton, have also turned up, and were published in last month's "Fraser's Magazine." It was instantly shown that these last were undoubted forgeries, and the source of some of them was very clearly indicated. We refer to this matter only to mention that a means has been discovered of deciding upon the age of a document up, at all events. to a certain time, and now it can be easily determined whether these documents are recent forgeries. M. Carré, the discoverer of this process, seems to have experimented with manuscripts of various ages. According to the lapse of time since the manuscript was written, he obtained fainter and fainter copies until he came to a document, dated 1789, of which he could obtain no copy at all. It may be accepted as a proof of the good faith of M. Chasles (of which, indeed, we have no doubt), that as soon as he heard of the process, he offered some of his numerous letters to be submitted to the proof, and we hope soon to learn whether or not M. Carré has succeeded in obtaining copies. The process is of a very simple kind, and, to say the truth, we are not disposed to put much faith in it. It is, in fact, nothing more than the ordinary mode by the press, but in place of using simple water M. Carré wets the document to be copied with dilute hydrochloric acid. What changes take place in ink which prevent us from obtaining a copy of a letter more than eighty years old, it is impossible to say. But supposing that ink containing iron has been used—and such inks appear to have been employed in Europe even in the time of Pliny—it might be expected after the application of hydrochloric acid an impression of a document of any date could be procured, which would be brought out and blackened on the application of a solution of tannin. This is, however, beside the present question, and we shall wait with some impatience to know the results of M. Carré's experiments with the Pascal-Newton documents.

We have alluded once or twice to the invention, by Dr. Kohn, of Breslau, of mica spectacles, to protect the eyes from injury by solid bodies, and also—mica being a very bad conductor of heat—from the mischief done to the eye by prolonged expo-sure to heat rays. The same eminent oculist has investigated the condition of the eyes of a number of compositors, and has made one or two practical suggestions, which are worthy of notice. The predominant affection of the eye produced in compositors is short sightedness, which increases with the length of time the occupation is followed. Out of 132 compositors whose eyes were examined, 68, or 51.5 per cent. were short sighted, and of these 51 had begun the trade with good sight. The source of the artificial light with which they work seems to have some influence on the production of the diseased state. Thus, of compositors who worked with oil lamps, 66 per cent. were short sighted, while, of those who worked with gas, only 50 per cent. were affected—a satisfactory state of things, considering that in this country little but gas is employed. The temperature in the neighgas is employed. bourhood of the ey of the eyes, when oil was used, was about 72deg. Fah.; and when gas was employed, about 76deg. Fah. The higher temperature, in the case of gas, was, no doubt, owing to the employment of the naked flame; and one of Dr. Kohn's suggestions is that the flame shall always be surrounded with a glass, which would, of course, arrest much of the heat. This would involve the use of the circular burners, but this, in the end, would, we believe, be found quite as economical as the bat'swing and fish-tail now employed. Another suggestion is an arrangement of the shade, to throw light more on the case, and less on the eyes of the compositor; and, lastly, the disuse of small types, with shorter hours of labour! These are all excellent suggestions, and, we may add, that it will be short sighted policy if they are not all adopted.

"FLINT JACK," the archæological curiosity manufacturer, has again turned up. He has been discovered at a village in Yorkshire, driving a roaring trade in forged implements and weapons.

ATTACK UPON THE PATENT LAWS.

N interval of about seven years has elapsed A since the last serious attack was made upon the principle of the patent laws. In 1862, Sir William Armstrong, at a meeting of the British Association, boldly assailed the theory on which they rest, and endeavoured to prove that public inconvenience ensued from the recognition of property in ideas. He had been hampered, he said, in manufacturing guns, by the patent rights of people whose inventions he wished to combine with his own. Captain Blakely, the inventor whose rights had been particularly obnoxious to Sir William Armstrong, urged, in reply, that he had been quite willing to lease his patents for a reasonable consideration; but this argument was looked upon as irrelevant by the supporters of free trade in other people's ingenuity. The necessity of buying inventions which he wished to adopt hampered the manufacturer, and to him it appeared that this objection was fatal to the whole system. It is satisfactory for those who wish to preserve for inventors the natural reward accruing to them from their intelligence and labour, to find, from the debate which took place on Friday in the House of Commons, that the opponents of the patent laws have not advanced beyond the position taken up by their predecessors seven years ago. The general drift of the speeches delivered by Sir Roundell Palmer and Lord Stanley was, that the patent laws were an inconvenience—that if all private property in ideas were confiscated to the public the public would be greatly the gainers. The "Pall Mall Gazette" on Saturday evening declared that this was equivalent to saying that if private property in land were confiscated the public would get the benefit of the crops. This simile is perfect, and puts in the clearest light the impolicy as well as the injustice of the proposed confiscation. All writers who have gone to the root of this question agree in admitting that a man who has evolved out of his own mind a valuable thought is the possessor of that idea just as completely as a carpenter is the possessor of the box which he has made with his possessor of the box which he has made with his hands. If any other man wants to use it he should buy it from the owner, and to take it away from him without giving him anything in return is simply an act of spoliation. But it is evident, on the other hand, that a practical inconvenience would ensue to the public if the inventor's ownership in the idea were prevental. Beyond this which the idea were perpetual. Beyond this, which would not in itself be a justification for depriving him of it, it is possible that some one else would have devised it sooner or later if the first inventor had not. Can it be right, therefore, that the public should be deprived of an inheritance to which it might have succeeded in any case, after the lapse of a few years, by an exaggerated respect for the rights of an individual? Manifestly not. A com-promise is therefore effected between the claims of private property and the convenience of the public. The original inventor is secured for a limited period in the enjoyment of the profit to be made out of his idea, and after this period has expired, his invention becomes the common property of all. A patent right is simply the name given to this admirable compromise, and the moral principle on which it rests can only be assailed by those who are prepared to deny the existence of all individual rights whatever. In defence of the principle involved in the patent

In defence of the principle involved in the patent law, it may be useful to quote the opinions of John Political Economy, he says, while objecting to monopolies in general:—"The condemnation of monopolies ought not to extend to patents.

This is not making the commodity dear for his benefit, put merely postponing a part of the increased cheapness which the public owe to the inventor, in order to compensate him for the service. That he ought to be both compensated and rewarded for it will not be denied, and also that if all were at once allowed to avail themselves of his ingenuity, without having shared the labour or the expenses which he had to incur in bringing his ideas into a practical shape, either such expense and labour would be undergone by nobody, except very opulent and very public-spirited persons, or the State must put a value on the services rendered by an inventor, and make him a pecuniary grant. This has been done in some instances, and may be done without inconvenience, in cases of very conspicuous public benefit; but in general, an exclusive privilege of temporary duration is preferable, because it leaves nothing to any one's discretion." The latter part of this passage deals with something more than the principle involved, and points out the way in which

the patent law indirectly promotes the welfare of that very public in whose interest it is proposed to sweep away the private rights of all inventors. Very of those inventions from which the public derives important advantages spring in complete maturity from the inventor's brain. It would be nearer the truth to say, that inventing is a business on which certain people enter, knowing that though the property which they hope to create, by the devotion of their time and capital to its pursuit, will, if they succeed in creating it, be of an exceedingly subtle and intangible nature, still, in a highly civilized state of society, like our own, they will be protected in its enjoyment, just as completely as if it were coal or iron dug out of the ground. If the strange sophistries on this subject were allowed to prevail, and if the patent laws were abolished, the obvious result would be that the progress of mechanical invention would at once be checked. Inventors, who are not themselves manufacturers, who are simply working out their ideas in order that they may ultimately sell their patent rights, would at once abandon the labour from which they could never hope to obtain a reward. Manufacturers who might invent new and useful processes would endeavour to guard themselves by a clumsy and artificial system of secrecy. If their inventions were of a nature which could not be concealed, the wealthiest manufacturers in their line of business would at once pounce on their ideas and absorb the lion's share of the profit. Other inventors, flying from a country, which, as far as their peculiar interests were concerned, would would be a land without laws, bring out their inventions under the protection of some foreign government, by which the rights of individuals were not tenderly treated, and Great Britain would lag behind all other states in mechanical and scientific progress.

It would be a work of time to follow Sir Roundell Palmer through each of his illustrations of the in-convenience ensuing to manufacturers from the necessity of respecting patent rights. One fallacy however, pervades them all. No manufacturer can be hampered by any patent right which he does not want to infringe, and if he wants to infringe it, that is to say, to use and profit by another man's invention, why should he be allowed to do so without paying the proprietor, any more than he is allowed to use another man's house without paying him rent? Take the case of the millers. R. Palmer says millers used to be greatly troubled by the flour flying about from the stones. They tried all manner of devices, with fans, to create an indraught, but it always sucked in too much air or too little. At last, someone invented a plan of doing this in the right way, and the millers seem to adopted his plan without paying him any royalty, to a very considerable extent, for we are told "all the millers in the kingdom combined to go into litigation to defend themselves, and suits of enormous magnitude resulted simply from this, that a man had been allowed to step in and prevent the millers from doing their business in the best way." But where would there have been room for litigation unless they had stolen the patentee's idea? If they had hit upon the same idea before him, his patent would have been invalid, and if they took the idea from him what possible justifi-cation can there be for them in attempting to profit by his ingenuity without paying him anything in return? If a patentee should prove a dog in the manger, not allowing any one to make use of his invention, nor carrying it out himself for the benefit of the public, the law ought certainly to make him do the one or the other; but in practice a state of things like this is unknown. If a man cannot apply his invention himself, he is only too glad to find some one who will take it off his hands, and he only defeats himself if he puts an exorbitant valuation on his right. Nothing would be easier, moreover, than to amend the patent law if that were found desirable, with the view of compelling patentees to lease their rights to any manufacturer willing to pay a fair price; but the plain justice of such an arrangement throws light on the gross injustice which would be committed if the patent right were annihilated altogether. As for the magnitude and costliness of litigation concerning patents, that simply illustrates the value of the property at stake which it is now proposed to confiscate. It is, no doubt, true enough that the ordinary courts of law are very bad tribunals for patent cases, and the great cost of such proceedings is an immense evil, which ought to be abated; but to abate it by giving up all that species of property to which it relates to public plunder would be like simplifying titles to land by abolishing landlords. It is fundamentally

untrue to say that the patent right is simply defensible as a stimulus to invention—to describe it in this manner as an artificial temptation held out to ingenious persons with the view of inducing them to make discoveries for the public benefit. An idea may be just as completely the property of the man who conceives it as the watch he wears in his pocket, and it is only placed under the protection of a peculiar law because its peculiar character renders it impossible for the policeman who protects the watch to protect also the idea. That the same idea may sometimes be conceived almost at the same time by different men is perfectly true; but it does not become any more, perfectly true; but it does not become any more, on that account, the property of the public at large. It may be difficult to say which of the two men is the owner; but one of the two is the owner undoubtedly, and the law gives the ownership to the man who first takes out a patent. If any one can suggest a better system of settling these difficult cases let him do so. Those who know most about the patent law will be the last to say that it is beyond the reach of improvement; but the only persons who would benefit by its total the only persons who would benefit by its total the only persons who would benefit by its total destruction would be powerful manufacturers, who would then be enabled to rob poorer inventors with impunity, and beat them out of the field by the power of purse. It is greatly to the honour of Mr. Mundella, who belongs to the only class which would benefit even temporarily by the abolition of the patent law, that he generously repudiates the unjust proposal.—"Standard."

# THE ARTIFICIAL PRODUCTION OF ICE

THE ARTIFICIAL PRODUCTION OF ICE AND COLD.

(Concluded from page 390.)

RROM what has been stated, it will be apparent that at present the choice of a refrigerating agent for producing ice or great degrees of cold, lies between ammonia, ether, and air, and that ammonia presents the greatest advantages for this purpose. The expansion of compressed air appears to have been the means first adopted for making ice, by Dr. Gorrie, of America; and in this country, ether was the material employed in one of the earliest ice-making machines invented by Harrison, in 1856. This was a very simple, but rather crude arrangement, represented by fig. 1, and consisting essentially of an air-pump C, connected with an evaporating vessel or refrigerator A on one side, and with a condenser on the opposite side, so that, by the action of the pump, ether was continuously vapourized in the refrigerator, while, at the same time, the vapour formed was withdrawn and forced into the condenser, where it was liquefied, and then returned to the

other was continuously vapourized in the refrigerator, while, at the same time, the vapour formed was withdrawn and forced into the condenser, where it was liquefied, and then returned to the refrigerator by a lateral pipe furnished with a valve. The fundamental principles on which this apparatus was constructed were correct, but there appear to have been several serious errors made in their application, and the plan did not come into use in this country. The ethermachine was afterwards improved by Messrs. Siebe, in 1862, and they have since applied themselves specially to the manufacture of these ice machines. Most of those which have been made were for India and other hot climates, where it has been found more advantageous to make ice by artificial refrigeration than to import it from America, owing to the large amount of waste by melting during the voyage through warm latitudes.

In the year 1860, another apparatus was invented by M. Carre, of Paris, in which a very strong solution of ammonia was used as the refrigerating agent. The arrangements of this apparatus provided for the condensation of the ammonia vapourized in the refrigerator, in such a way, that it was used over and over again, and the operation of the apparatus was continuous, as in the case of the ether machine. The woodcut, fig. 2, represents this apparatus. A strong vertical boiler Ais charged with a concentrated solution of ammonia, to which heat is applied, under a pressure of eight or nine atmospheres—100lb. to 1351b. per square inch—and the mixture of gaseous ammonia and steam produced passes off through an ascending coil of pipe B, attached to the upper end of the boiler, into a tubular condenser D, surrounded by cold water, where the distillate is cooled and liquefied under the pressure above stated. The condensed liquid collects in a receiver z, and thence passes by the pipe eee into the refrigerator F, at a rate which is regulated by a special contrivance.

The refrigerator F consists of a close vessel with tubes f, closed at the bot

#### PRODUCING COLD. MACHINES FOR

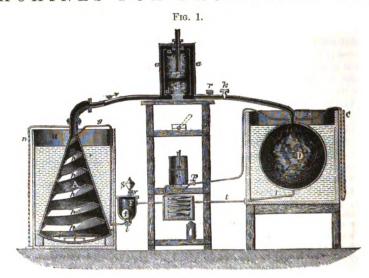

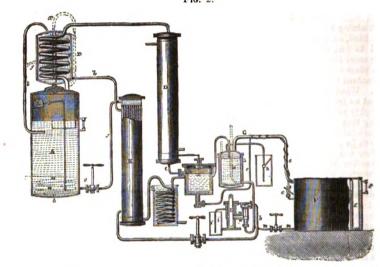

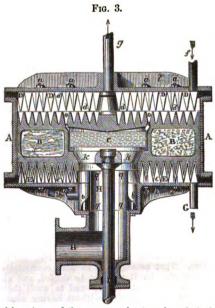

Fig. 2.

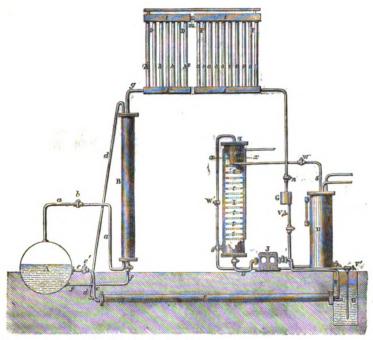

refrigerator, and the pressure kept so low that the liquid ammonia is vapourized continuously, thereby abstracting heat from the contents of the tubes f. The solution of ammonia produced in the absorber H is forced by the pump I through the pipe b into the outer casing of a tubular vessel K, called the regenerator, through the tubes of which hot water, exhausted of ammonia, flows in the opposite direction from the boiler A. Here an interchange of temperature takes place, the solution of ammonia becoming heated while the exhausted liquor is cooled. The solution of ammonia, thus heated, then passes on into the closed vessel above the boiler, and containing the coil B, where it is still further heated, while the gaseous ammonia and

steam within the coil B are partially cooled and condensed, and it then flows by the pipe b into the boiler A to serve for a repetition of the process.

The hot liquor exhausted of ammonia meanwhile flows from the boiler in a regulated current through the pipe J into the tubes of the regenerator K, thence through a cooling worm m surrounded by water, where its temperature is sufficiently reduced, and then passes into the absorber H, furnishing the supply of water for dissolving the ammonia as already described. This machine has been largely used in the south of France for effecting the crystallization of salts by cooling, and several have been sent out to India for making ice. In 1862, Mr. Kirke, of the Bathgate Chemical Works, invented a machine in which the alternate compression and expansion of air was applied as the means of refrigeration, on the in which the alternate compression and expansion of air was applied as the means of refrigeration, on the same principle as Stirling's air engine for obtaining motive power. This machine, which is represented by fig. 3, has been used in paraffin oil works for effecting the separation of solid paraffin from the oil; it has also been worked at Messrs. Flower's oil; it has also been worked at Messrs. Flower's brewery at Stratford-on-Avon, and one has been sent to China for making ice. The arrangement of the machine is very good; but, for making ice, it is expensive, on account of the relatively large expenditure of power required. Messrs. Mort and Nicolle, of Sydney, in Australia, have quite recently patented another apparatus, in which the expansion of cold compressed air is proposed to be applied; but the principle on which it is based appears to be erroneous, and it is not likely to be effective for refrigeration, besides which their apparatus is far too complicated in its arrangements. Several other patents have been taken out for ice-making machines, but those already mentioned are the principal ones which have been tried.

#### MACHINES FOR PRODUCING COLD.

of plates arranged one above the other inside. Into the top of this vessel a concentrated solution of ammonia is pumped continuously, and, in descending from plate to plate, it meets the ascending current of high-pressure steam, the effect of their contact being to convert the ammonia into gas, while the steam is condensed and flows back again to the boiler A. The gaseous ammonia passes out of the analyzer by the pipe g into a tubular rectifier D D, where the remaining steam is condensed and separated, while the ammonia passes on through a condenser F F, where it is liquefied, and then flows through the pipe c to the refrigerator H, the supply being regulated by a cock n.

Meanwhile, a regulated current of spent liquor passes from the boiler into a long tube C, called the heater, fitted with an internal set of tubes, through which the concentrated solution of ammonia is forced by the pump J into the top of the analyzer. By this means the solution of ammonia is heated, and, at the same time, the hot liquor from the boiler is sufficiently cooled to be supplied to the absorber I, into which it is forced by the pressure of the boiler, through the pipe x x, fitted with a cock w, to regulate the supply. In the absorber I, this water becomes saturated with gaseous ammonia discharged from the refrigerator H, and the resulting strong solution of ammonia is then pumped out into the analyzer. The important feature of this arrangement consists in the application of the analyzing column B, and the rectifier D D, by which it is intended that the dehydration of the ammonia should be carried so far that the condensed liquid passing into the refrigerator may be practically free from water, while, in Carre's apparatus, the liquid supplied to the refrigerator and only 75 per earl of water and only 75 per and 10 means and 10 m

far that the condensed liquid passing into the refrigerator may be practically free from water, while, in Carre's apparatus, the liquid supplied to the refrigerator contains 25 per cent. of water, and only 75 per cent. of actual ammonia.

The effect of this difference upon the working of the apparatus would be very great. Thus, for instance, the distillate passing from the boiler of Carre's apparatus is separated into 95 per cent. of a liquor containing 25 parts of ammonia—which, after being cooled, is used for supplying to the absorber—and 5 per cent. of a distillate consisting of 3-4ths ammonia and 1-4th water, which passes through the condenser without any further separation of the water. Therefore, only 3-4ths of the liquid supplied to the refrigerator is ammonia; and since water, at the temperature of from 22deg. to 40deg. Fah., which is produced in the refrigerator, is capable of dissolving and retaining in solution its own weight which is produced in the refrigerator, is capable of dissolving and retaining in solution its own weight of gaseous ammonia, only 2-3rds of the ammonia in the liquid supplied to the refrigerator will be available for refrigeration, the remaining third being retained by the water in that liquid, so that there will be a residuum of solution of ammonia, which must be run off from time to time from the refrigerator. Therefore, since the effective refrigeration in an apparatus capable of making 5cwt. of ice an hour from water at 60deg. Fah., must be equivalent to the vapourization of 106lb. of ammonia within that time, it would be requisite to produce in the condenser a distillate at the rate of 212lb. per hour, for of this quantity 53lb. will be water, and that water will retain 53lb. of ammonia in solution, leaving only 106lb. available for refrigeration. Then, since the cooled exhaust liquor, as introduced into the absorber, already contains 25 per cent. of

ammonia, it will dissolve only 1-20th of its weight ammonia, it will dissolve only 1-zoth of its weight more of ammonia; and consequently, to maintain the required rate of vapourization, it will be necessary to supply at the rate of 200 gallons exhaust liquor per hour to the absorber,\* and to pump nearly 1 ton of ammonia solution per hour into the boiler, against a pressure of ten atmospheres, which will require an expenditure of power to the extent of ½-horse power per hour.

an expenditure of power to the extent of ½-horse power per hour.

In the apparatus devised by Mr. Reece, on the contrary, it is proposed that the ammonia solution should be separated by the operation of the analyzer into 75 per cent. of liquor, containing five parts of ammonia, which is to return to the boilers, and into 25 per cent. of gaseous ammonia, which, after being completely dehydrated in the rectifier, is to be deligrated to the refrigerator, almost early why for free. completely denydrated in the rectiner, is to be de-livered to the refrigerator almost entirely free from water. In this case, therefore, 5-6ths of the ammonia distilled would be available for refrigera-tion, while, in Carre's apparatus, not more than 1-24th of it is available. Then, since the exhaust 1-24th of it is available. Then, since the exhaust liquor in Reece's apparatus would contain only 5 per cent. of ammonia instead of 25 per cent., as in Carre's apparatus, it would be capable of dissolving a further 20 per cent. Consequently, for the same amount of work, only 1-5th as much would be required as in Carre's apparatus, and there would be only 1-5th as much solution of ammonia to be pumped back into the analyzer. These are advantages of a very striking and important nature, and, if realized practically, they would offer for the first time an opportunity of utilizing to the fullest extent the great capabilities of ammonia as a refrigerating agent, in such a way as to surpass all others in efficiency.

agent, in such a way as to surpass all others in efficiency.

Little has hitherto been done in the application of artificial refrigeration to the making of ice in this country; but in hot climates, remote from natural sources of ice, it has been found to work very advantageously. Apart, however, from the actual production of ice, which, from our proximity to Norway, can be cheaply obtained thence in great abundance, there are many other purposes for which artificial refrigeration can be of great service. In preparing salt meat, for instance, a certain degree of cold is required to enable the meat to take the salt, and, in this case, the use of an apparatus capable of producing cold at pleasure would do away with the expense attending the transport and storing of large quantities of ice. Again, the influence of cold in preserving meat, fish, and other provisions, is sufficiently well established to justify the belief that artificial refrigeration might be applied with great advantage, not only in the transport of such materials for the context to the context to the materials for the context to the context to the context to the context to advantage, not only in the transport of such materials from the country to the metropolitan markets, so as to ensure their arrival in better condition, but also as a means of compensating that uncertain and variable relation between supply and demand which variable relation between supply and demand which sometimes renders articles of food excessively dear, and at others reduces their value to almost nothing. Large quantities of provisions are constantly being destroyed as unfit for food on account of damage during transport, or from being kept too long, and this might, in all probability, be prevented, if suitable means were applied to keep them cool while

\* See Report by Regnault, Balard, and Pouillet, "Comptes Rendus," 1862.

being brought to market, and to store surplus supplies at a sufficiently low temperature for their preservation. Enormous quantities of fish are at times destroyed or carted on the land for manure, times destroyed or carted on the land for manure, because, in the absence of any means of preserving an unusually large supply, it is not worth the cost of transport to market. In like manner, the importation of what may be called the waste meat of the Australian colonies, South America, and of other

portation of what may be called the waste meat of the Australian colonies, South America, and of other countries, appears to depend mainly on a practical solution of the problem, whether a sufficiently low temperature for preserving the meat fresh can be maintained during the passage to England, at such a cost as would afford a profit on the trade.

Another of the purposes to which artificial refrigeration may be applied with advantage is the brewing of beer, especially as the necessity for cooling power is of uncertain occurrence, and varies very much, according to the season, so that there is too great a risk in keeping a store of ice for the purpose, to admit of its being so much practised as might be desirable. It is, indeed, remarkable that so little has been done hitherto by brewers in applying artificial refrigeration, for with the exception of Messrs. Flower, of Stratford-on-Avon, who were the first to put up a machine for this purpose, and of Messrs. Truman, Hanbury, and Buxton, who have lately put up one of Siebe's ether machines at their brewery, there is, perhaps, no other brewery where browery, there is, perhaps, no other brewery where artificial refrigeration is practised.

The practical benefit of such a means of producing

artificial refrigeration is practised.

The practical benefit of such a means of producing cold at will, without incurring the expense arising from the waste of ice kept in store, has been well illustrated by the results obtained by Mr. King, the engineer to Messrs. Truman's brewery, during the autumn of last year. The apparatus worked there is capable of producing five tons of ice within the twenty-four hours, with a consumption of coal at the rate of ten tons per week, or about 7s. per ton of ice produced; and the additional cost corresponding to expenses for labour, waste of material, and interest on first outlay, would probably fall far short of the average price of ice during warm seasons, when it is most in demand, and sometimes rises as high as £2 per ton. But this is not the whole of the advantage capable of being realized in such a case by applying artificial refrigeration. In many cases it is by no means necessary for the object in view to produce ice, and in fact, there may be a very great advantage gained by not doing so. Thus, for instance, Mr. King has, by an ingenious contrivance, arranged the working of his apparatus in such a manner that the refrigeration is applied directly to the material to be cooled, without making ice or using any refrigerating medium; and by this means he has succeeded, with the apparatus just referred to as capable of producing five tons of ice in twenty-tour hours, in obtaining, during the same time and with the same consumption of fuel, an effect equivalent to the production of no less than fourteen tons four hours, in obtaining, during the same time and with the same consumption of fuel, an effect equivalent to the production of no less than fourteen tons of ice. This reduces the cost of the work done very considerably below the estimate already given, and the fact serves well to show what great benefit may be derived from the judicious application of refrigerating apparatus. rating apparatus.

rating apparatus.

Among other purposes to which it has been proposed to apply artificial refrigeration, is the cooling of the air in dwellings, and in passenger ships passing through tropical regions; and there are, no doubt, many other cases in which it might be usefully employed.

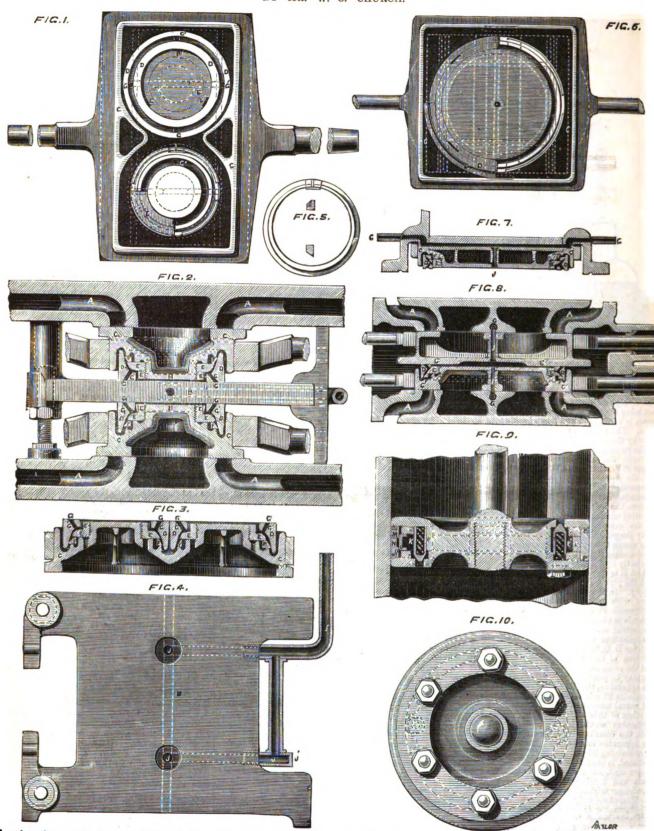

fully employed.

### CHURCH'S PATENT SLIDE VALVES AND PISTONS.

N our notice of the conversazione at the Insti-In our notice of the conversazione at the Institution of Civil Engineers we have briefly referred to the improvements which have been effected in slide valves by Mr. W. C. Church, of 2, Whitecross-place, Wilson-street, Finsbury, and 5, Church-street, Derby. This important subject demands special attention, and we therefore propose to place full particulars of this patented invention before our readers, illustrating the same by the annexed engravings. In these, fig. 1 is a plan or horizontal view of a slide valve constructed for the annexed engravings. In these, fig. 1 is a plan or horizontal view of a slide valve constructed for two caps or rings. One cap is shown in its proper position, and the other is removed, showing a quarter of the junk ring. Fig. 2 is a vertical section through the steam chest of a double cylinder engine, in which one steam chest supplies both cylinders with steam. Fig. 3 is a section at right angles to fig. 2. Fig. 4 represents detached the division plate, with the pipes for carrying off any leakage of steam between the back of the valve and the inside of the cap. Fig. 5 represents the metallic packing ring detached. Figs. 6, 7, and 8 show an arrangement of the valves for dispensing with the division plate in the steam chest, by making the two valves work back to back. A A are the steam ports, B is the division plate, C C are the slide valves, D D the caps or rings applied to the back of the slide valves, E E the junk rings, F F the metallic packing rings

#### PATENT SLIDE VALVES AND PISTONS.

BY MR. W. C. CHURCH.

for keeping the caps D D steam tight.

for keeping the caps D D steam tight. In describing the action of these improved valves, we must premise that the object of the cap is to prevent the steam in the steam chest from acting on that part of the back of the valve which is enclosed within the caps, or, more strictly speaking, that area which is represented by the line of contact between the caps and the metallic packing rings.

The cap is of a conical form, both internally and externally. The object of this form internally is to enable the metallic packing ring F to act as an expanding ring, in order to press the cap up to the division plate B (or the second valve) when the steam is shut off from the steam chest. The circular groove G and the holes G l in the cap D, and the holes E l in the junk ring E are intended

to carry off all steam that may leak between the surface of the cap D and the division plate B (or the second valve) at a part of the cap that will prevent the occurrence of a pressure to remove the cap from off its bearing face. When the steam is in the steam chest, the cap D is pressed up against its bearing face by the steam on the annular area, which is equal to the difference in diameter between the metallic packing ring F and the cap D. The caps D D are free to move on a fixed centre, at a point H, so as to compensate for unequal wear of the valves of the cap face, or for one side of the valve to lift in case of the engine priming. The metallic packing ring F is also arranged in such a manner as to be capable of accommodating itself

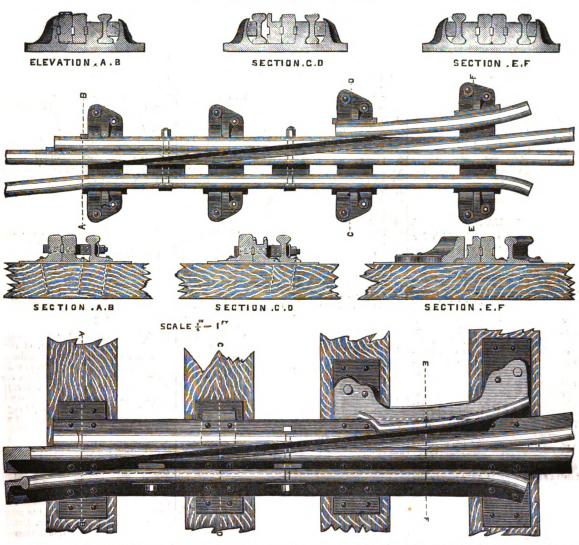

The ring is so arranged that the steam presses it both outwards against the cap D, and upwards against the junk ring E.

The metallic packing ring F is also made conical

on its outer circumference, for two reasons: first, in order to reduce the area of superficial contact between itself and the cap D; and, secondly, in order between itself and the cap D; and, secondly, in order to give the steam a larger area to act upon at the bottom of the ring; so that no amount of leakage on to the top of the same shall be able to place it in equilibrium, and thus destroy its required action. The holes, passages, and pipes J and J<sup>1</sup>, in connection with the division plate B, are intended for carrying off any steam that may accumulate for carrying off any steam that may accumulate in the cap D. The pipes  $J^{-1}$  are in communication manner as to be capable of accommodating itself to the varying position either of the cap or valve.

#### IMPROVED RAILWAY CROSSINGS.

MR. R. PRICE WILLIAMS. BY

so that in the event of any accident occurring to the caps D, these cocks can be closed. The effect of this will be merely to alter the action or condi-tion of working the valves, and reduce them to valves of the old construction. The division plate B is adjusted in position as required at the back end of the steam chest, by means of set screws, as shown in fig. 2, and at the front end by means of two brackets fixed to the steam chest lid, so that when the steam chest lid is removed, the valves can be withdrawn in the usual way without disturbing the division plate. Another mode of fixing the division plate is to slide it into a groove provided for it in the top and bottom of the steam

Figs. 6, 7, and 8 show an arrangement of the valves for dispensing with the division plate in the valves for dispensing with the division place in the steam chest, by making the two valves work back to back. In this case only one valve is required to have a cap on the back of it, the other having a plain surface for the cap to work against. Provision is made in these valves for allowing any steam that may accumulate in the cap D to pass out into the atmosphere, by means of the passages J and G in the centre bar of the exhaust ports and the centre bearing of the valves. The valves and ports are so arranged in figs. 7 and 8 as to reduce the steam ports in length as much as possible, and thus reduce the amount of steam used for charging the ports at each reciprocesting movement of the the ports at each reciprocating movement of the piston. The sides of the ports are extended in a circular form, in order to avoid the caps overhanging the faces of the ports at the end of their stroke.

We will now proceed to state a rule by which Mr. Church determines the area of the cap to be applied to the back of the valves. That portion of a slide valve which does not leave the face of the ports at the end of the stroke, less the area of the steam ports, represents the area on the back of the valve, upon which there is a constant pressure, varying only with the pressure of steam in the boiler. And as it is the object of Mr. Church's

improvements to remove this pressure, it becomes desirable to point out the following rule for determining the area of the back of any slide valve, from which the pressure may be removed, by the application of a cap as described.

Let A equal the area of that part of the valve that leaves the face at the end of the stroke.

Let C equal the total area of the steam ports.

Let D equal the area of the annular cap or ca for removing the pressure from the back of the

Then the formula will stand as follows:

Then the formula will stand as follows:—

A—(B+C)=D.

To take an example—Let a slide valve be supposed measuring 11½in. by 19in. The total area of the back of the valve would be equal to 213.75 square inches. The area of that part of the valve which leaves the port faces at the end of the stroke may be taken in this case as equal to 43.75 square inches. The total area of the two steam ports is equal to 49.50 square inches.

square inches.

Then 213.75—(43.75+49.50)= 120.50 square inches; which shows the area of the cap or caps to be applied to the backs of the valves, or, more strictly, the area to be contained within the circle described by the line of contact between the cap

or caps and the elastic metallic packing ring.

These valves can be applied to any description of engine at present in use, either stationary, marine, or locomotive, In this latter respect they have been used on the Great Northern Railway with satisfactory results, as will be seen from the following report of working from Mr. J. Budge:—

### GREAT NORTHERN RAILWAY.

(Signed) J. Budge.

Besides the slide valves, Mr. Church has effected some improvements in pistons, which are illustrated in figs. 9 and 10, which are a section and underneath plan. K and K 1 are two small valves so arranged that one is in communication with the arranged that one is in communication with the steam on one side of the piston, and the other with that on the opposite side at each reciprocating movement of the piston. By means of these valves the steam is allowed to pass into an annular chamber enclosed by the ring L, thereby pressing against the inside of the ring, and forcing the packing rings M N and O outwards against the inside of the cylinder. Owing to the taper form of the rings N and O, they become pressed outwards laterally, as well as towards the inside of the laterally, as well as towards the inside of the cylinder.

The segments P P are for breaking joint in the packing rings M and O. It will be seen that the area of the ring L, upon the inside of which the steam acts, is much less than that of the bearing

surfaces of the packing rings M N and O; and it can be limited as desired just to keep the rings close against the inside of the cylinder and no more, by which means the wear and friction are reduced to a minimum. The small valves K and K 1 are so arranged as by their respective closing to prevent the escape of steam from the annular chamber in the piston as it leaves the cylinder at either end. The valves are also arranged so that the annular chamber may receive a fresh supply of steam from either side of the piston, in order to keep up a constant pressure on the packing rings during the whole time that the engine is at work instead of a merely intermittent pressure as usual in steam-packed engines. In some cases Mr. Church makes the ring L in two halves, in which case the junk ring G may be dispensed with, the construction of the piston thus being much simplified for small engines. Mr. Church has also patented some improvements in safety valves, the description of which we reserve for our next.

### PRICE WILLIAMS' RAILWAY CROSSINGS.

T would seem clear from the models which Mr. Price Williams exhibited at the late conversazione of the Institution of Civil Engineers, that railways, as at present constituted, are much open to improvements, in the matter, at least, of switches and crossings. In our general notice of the conversazione, we have given the leading features of the switch model, and do not dwell upon it further here than to remark that it is singular to find two such useful and novel inventions included under one patent. Both the crossings and switches are the design of a practical man, well acquainted with the deficiencies of the existing materials, and determined to rectify them; at all events, in such points as are more obviously defective. The long experience of Mr. Price Williams in the maintenance of permanent way has admirably qualified him for the post of inventor in this department, and now bears fruit in the improvements to which we refer, for the soundness of which the name of the inventor would be to many a sufficient guarantee. When it is considered that the number of inventions in the matter of permanent way is very great, and that these inventions in general deal only with very trifling details, it is satisfactory to notice improvements which deal with the main principle as well as with the details. This is the case with the inventions in question; and in the expectation that they will hereafter play a part in our railway system, which so nearly concerns the safety of all. we lose no time in placing before our readers the details of these crossings.

Before, however, proceeding to the description of the improvements themselves, it may be well to refer to the crossings most commonly found on railways, and the points in which they need improvement. Most of our readers are doubtless well acquainted with the solid cast-iron crossings, which have been widely employed. These are, theoretically, very perfect; the point is well defined and solidly united to the body of the crossing, and the whole crossing has a smooth and neat appearance, which go far in its favour when it is seen laid in the permanent way. But this crossing has very serious defects; that which is most complained of is the rigidity and want of elasticity in the large cast-iron block which composes the crossing. From this cause arises damage to the rolling stock and jolting to passengers. Another defect is the want of ready and convenient attachment to the rails, which is seriously felt in laying-in the crossings. The third defect is the brittleness of the point, which readily gives way to a sudden blow, and the crossing is then spoiled. Most of these defects are common to all solid crossings, and have led to a very general disuse of crossings of this form. The type of crossing most commonly adopted is the V-piece crossing. In this case, the main line rail and the siding rail are united at the point, and there terminate. The objection to this arrangement is that the point is not sufficiently supported and held down; consequently, the point is apt to get canted up and loosened, and by the frequent hammering action of the engines is then soon destroyed. It is true that special devices have been adopted in certain cases with more or less success, but their effect is only partial, and the best of these is far inferior in compactness to the crossing which we now describe, and which is illustrated in the annexed engraving.

The conspicuous feature in Mr. Price Williams crossings is the through rail for the main line. The

crossing is formed of two steel rails, one for the main line and one for the branch line. That for the main line is continued through the crossing, while that for the branch is brought up to the main line rail and bent alongside of it to the angle of the crossing. These two rails are firmly bolted together, and a slot is cut through both to the depth of 12in., to admit of the flange of an engine crossing the main line rail. This slot, it is to be noticed, does not disable the rails, which are rolled solid, and are only cut through to the extent of little more than one-fourth of their section. These two rails, with the adjacent guard rails, form the entire crossing, which is firmly bolted together and laid in the same manner as the other parts of the road, either in chairs or on sleepers, as the case may be. details of the arrangement may be easily gathered from the engraving. One of the figures represents a crossing as adapted to a double-headed rail, and a chair system similar to that used on the South-Eastern Railway. The other shows a crossing as adapted to a flat-bottomed rail, such as is used on the Metropolitan Railway. There is no difficulty in adapting it to any other description of permanent way, as, for instance, that where iron sleepers are used, and in this respect it will be very valuable in countries where timber is scarce and very

From the above description it will be seen that this crossing is free from the defects to which we have alluded in speaking of the crossings at present in use. The crossings here described is it should be, a continuation of the road. There is no abrupt change of material, nor of elasticity; the crossing is laid exactly as the rest of the road is laid, and would scarcely be noticed in passing over it. The continuous rails which compose the crossing are fished up to the adjacent rails in the road, and this fastening ensures the position and security of the crossing, while the point cannot fail to be sound, and is incapable of shifting in any direction. Thus the crossing fulfils the three great conditions of durability, elasticity, and ease of attachment to the road, combined with cheapness and general simplicity. Such a combination of useful qualities is valuable in the highest degree, and will, we doubt not, be speedily appreciated by practical men.

# THE ROYAL HORTICULTURAL SOCIETY.

THE great flower show of the season was opened the gardens of the Royal Horticultural Society, at South Kensington, on Wednesday last, the display being really magnificent. The new plants exhibited by Messrs. Veitch wore:—Duvallia Morei, Croton Veitchii, C. acubæplina, E. Hillianum, Begonia Sedeni, small leaved, with a delicato red flower; Masdevallia coccinea, M. Veitchiana, Iresine, Lindeni, Phormium Colensoi, Nepenthes rubra, the yew-like Retinospora filicoides, Darwinia fimbriata, Duvallia hemiptera, Dracana negro rubra, Thusia Bensonia. Those by Mr. B. S. Williams were Cochliostemon Jacobianum, Cymophyllum spectandrum, Epidendrum pentoles, Calamus ciliaris, Areca nobilis, Gesnoma Zamariensis, Araucaria elegans, A. Rulei, Ptoris serrulata corymbifera, Oncidium altissimum Cattleya citrina, Quercus concordia, Lælia pur-purata, Cypripedium barbatum superbum, and altissimum, and Lælia marginata (pale pink flowers), and Littonia modesta (orange yellow)—the last two the first time shown, and rewarded with first-class certi-ficates. There were also first-class certificates time shown, and rewarded with first-class certificates. There were also first-class certificates awarded to Messrs. Downie, Laird, and Laing, of Forest-hill, for Colous Saisonii (pink and white flowers), and a new double pelargonium, with very bright scarlet flowers, called "Victor Lemoine;" to Mr. Turner, of Slough, for the following pelargonia:—"Bright Star," scarlet; "Marmoin," scarlet, round crisp flowers; "Lady Carrington," sea pink and white very delicate. "Marmoin," scarlet, round crisp flowers; "Lady Carrington," pale pink and white, very delicate; "Corsair," deep red large flowers; "Maid of Honour," magnificent flowers, more than 23in, in disputator in colour flowers. in diameter, in colour, strong pink and delicate red; "Pretender," madder and crimson; "Sulred; "Pretender," madder and crimson; "Sultana," madder and pink; "Her Majesty," beauround and well-formed, pink and red; arrior," scarlet and madder; "Holkar," deep tiful Warrior," "warrior," scarlet and madder; "Holkar," deep lake and pink; "Gratulation" of the same class of colour, but redder; "Bonnie Charlie," similar, but deeper in colour. An exquisite series of varieties of British ferns was contributed by Mr. Lowe, F.R.S., of Nottingham, and first-class certificates were awarded to him for the following: —Scolopendrium vulgare, varieties summum, Thompsonii ornamentum, Allokoton dividendum,

Killiston gloriosum, Ath varieties Rickettsiæ, kalon. Athyrium filix fomina,

Not less attractive than the flowers was the collection of fruit, which was very good, grapes, pineapples, strawborries, peaches, &c., presenting a very tempting appearance. Of course, the great attraction was the annual exhibition of rhododendrons, under the great tent (by Mr. Anthony Waterer, of Knap-hill, Woking), which always proves of fresh interest to the visitors. Mr. Waterer has been particularly successful in producing novelties in this magnificent flower, and there are a large number in the present collection, showing very decided improvements in form and colour upon any yet introduced. The monster tent, 300ft. long, 120ft. wide, 55ft. high, and covered with 40,000 square feet of canvas, is admirably adapted to show off the variety of colours to the best possible advantage; indeed, on a fine day, the view from the high ground at the entrance is one of the finest. It affords us much pleasure to announce that the Council of the Horticultural Society, on Wednesday, awarded Mr. Wateror the gold medal of the society. It is richly deserved, and the more so, on account of the generous feeling that has restrained that eminent practical florist from competing for any prizes. The show remains open for several days, and as the rhododendrons are not yet fully out in blossom, it will increase in beauty by the end of the week.

### BEVIS' FEATHERING SCREW.

MR. R. R. BEVIS, the managing engineer to Messrs. Laird Brothers, of Birkenhead, has patented an arrangement for feathering the screw propeller, which has just been practically tested in the "Kathleen," a yatch built for the Marquis of Downshire, by the above firm. Mr. Bevis had long seen that a screw of the ordinary kind, whether fixed or revolving, was a heavy drag against speed and handiness of sailing; and that a lifting screw was a somewhat complicated and costly piece of mechanism. He, therefore, worked out a method of feathering the blades in a fore and aft direction, which appears to have answered satisfactorily. The "Kathleen" is of the following dimensions:— Length between perpendiculars, 140ft.; width, 22ft.; tonnage, 326 tons; and is fitted with a pair of inverted cylinder surface condensing engines, of 60-horse power nominal, and has capacity for about 70 tons of coal in her bunkers. Draft of water 11ft. abaft and 8ft, forward. She is rigged as a fore and aft schooner, with a good spread of canvas. accommodation for the owners is arranged in a halfpoop, about 55ft. long, and there are also additional cabins forward, as well as state-rooms for the officers, and a good forecastle for the crew. On the occasion of the trial, she had a draught of water of 11ft, lin, aft and 8ft, lin, forward, with a displacement of 316 tons, and an area of section of 148ft. The speed obtained as the mean of runs at the measured mile was 11:27 knots, with an indicated power of 393-horse power, the number of revolutions being 121 per minute. Before making the trial at the measured mile, a short trial made under sail alone, with the blades of the screw feathered into a fore and aft line, the operation of feathering the blades occupying only three or four minutes, and afterwards with the blades fixed to a pitch of 104ft. It was found that with the screw feathered, the yacht not only had a speed of 13 to 2 knots more than with the screw fixed, but that she was more lively in coming round. It was thus shown that the drag of the screw not only affected the speed through the water, but prevented the ship working as satisfactorily as she did when the blades of the screw were feathered fore and aft. The gear for feathering the blades is well protected, being worked in the screw-shaft tunnel by a rod passing through the centre of the shaft, and the levers that move the blades are enclosed within the boss of the screw propeller.

THE distribution of prizes to the students of the medical department of King's College, took place on Wednesday afternoon. The Archbishop of Cauterbury presided, and there were present the Bishop of London, Dr. Jelf, and Dr. Barry, the members of the council, and a number of ladies and gentlemen. Barry tendered a hearty welcome to the Archbishop on his taking the chair, and said that his Grace was no stranger within the walls of the institution. Dr. Barry spoke very encouragingly of the progress which the students had made during the past year in secular as well as in religious knowledge.

# OFFICIAL TRIAL OF THE LIQUID FUEL PLATE FURNACE AT CHATHAM.

THE method of heating armour plates for bending by means of liquid fuel, as applied by Messrs. Dorsett and Blythe, in Chatham Dockyard, and the successful results of the experiments, are, doubtless, fresh in the minds of our readers. We, therefore, without further comment, append a tabulated statement of the results obtained during an official trial, on the 26th ult., of the Dorsett system against the ordinary system of plate heating. These results will be found, on analysis, to be highly favourable to the liquid fuel system:—

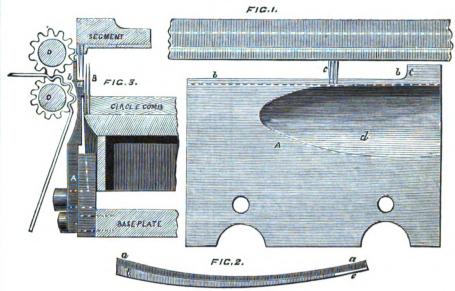

Experiments on Plate Heating by Liquid Fuel against coal, made at Chatham Dockyard, May 26, 1869:—

# WOOL COMBING MACHINERY.

BY MR. I. HOLDEN, M.P.

# ATTEMPERATOR FOR UNION CASKS.

BY MR. J. STIRK.

## IMPROVEMENTS IN COMBING WOOL.

MR. ISAAC HOLDEN, M.P., of Oakworth House, near Keighley, Yorkshire, has patented some improvements in apparatus for combing wool, in which are employed in connection with the carrying or holding combs other combs (which he calls "nacteur combs"), whose teeth point in the opposite direction to and during part of their motion overlap the carrying combs. His improvements also include the use with these combs, of a guard plate, formed with a projecting ledge in order that it may, whilst bearing against the carrying combs, give support or protection to the points of the nacteur combs during the drawing off of the fibre through the teeth of both combs. The plate extends in a direction from the tangential point of the carrying comb and the drawing-off rollers to the part of the carrying comb at which the long fibres begin to be drawn through the two combs by the drawing rollers, and also to some distance in the opposite direction. Part of it is also formed to act in cutting off or arresting the drawing off from the carrying combs of the longer fibres er top. This plate is also cut away in part to admit of the lower of the drawing-off rollers

In our engraving, fig. 1 is a front view, fig. 2 a plan or upper edge view, and fig. 3 an end view of a guard plate in position. A is the guard plate, B the carrying or holding combs, and C the nacteur combs. The guard plate A is formed with a projecting ledge a, adapted in working to give support to the teeth of the combs B, at the time of drawing off of fibre through the teeth of both of the combs B and C by the drawing rollers D. The projection b is that which affords protection to the points of the teeth of the nacteur combs C. The part c of the guard plate A is that which acts in cutting off or arresting the drawing off of the longer fibre or top. The part d of the guard plate A is cut away or recessed to admit of the lower of the drawing-off rollers D coming closer up to the main circle of teeth.

# STIRK'S ATTEMPERATOR FOR UNION CASKS.

MR. JOSEPH STIRK, the engineer to Messrs.

Alsopp and Co., at their new brewery, Burtonon-Trent, has invented a simple and efficient
attemperator for union casks, which is illustrated
in the annexed engraving, which we take from the
"Brewers' Journal." The apparatus is a flat copper

tube, in which partitions are inserted, through which a stream of water travels. Fig. 1 is a longitudinal and fig. 2 a transverse section of the apparatus; fig. 3 a cask in part section, showing an edge view being a cask in part section, snowing an eage view of the attemperator, and fig. 4 an outside end view. A stream of water entering at the inlet opening has to traverse the length of the tube four times, as shown by the arrows in fig. 1, before reaching the outlet. At each end of the tube is a brass casting; shown by the arrows in fig. 1, before reaching the outlet. At each end of the tube is a brass casting; one of these is provided with unions for attaching the inlet and outlet pipes, and the other has a socket which fits on a brass stud projecting from the opposite end of the cask, as seen at fig. 1. The head of the cask, through which the attemperator is inserted, is fitted with a brass casting, as shown in section at fig. 1, and in elevation at fig. 4. The attemperator is attached to this casting by six studs, the whole forming a compact and efficient arrangement.

#### AERONAUTICAL SOCIETY OF GREAT BRITAIN.

(Continued from page 385.)

DR. SMYTH wished to correct a mistake. Tt seems to be taken for granted that the muscles of the legs are stronger than all others. The power which those muscles are capable of exerting are really less. Muscles are stronger in proportion as they are stronger, and the muscles of the arms, when well developed, are immensely

strong.

Mr. Quartermaine said it might be important to observe that a pigeon will weigh about 11b. and have little more than a half square foot of surface. The weight of a bird is enough to propel it at a moderate velocity by three or four strokes per second, and driving it through 90ft. or 100ft. in the same time, so that a pigeon can fly 60 or 70 miles an hour without the use of more than the 250th part of a horse power per minute. That was, therefore, equivalent to more than forty times the power land. It should, however, be borne in mind that, with an equal additional weight to that of the bird, a pigeon would fail to fly at all. With a weight equal to their own, they would not be able to raise themselves from the ground more than momentarily. A horse would draw a load equal to his own weight at a much greater proportional velocity than a bird could do.

In reply to Mr. Kaufmann, the speaker said that one one-horse power in air would produce an effect equal to the expenditure of 40-horse power on land. Mr. J. M. Kaufmann, C.E., read a paper entitled

"A Few Remarks upon Aerial Transcursion":-Since the last occasion I had the pleasure of addressing you, considerable leisure has enabled me to arrive at certain conclusions materially altering the (at present) existing arrangement and power of my machines. By referring to these (photographs handed round), you will be better able to follow my subject. The only laws which we have imperatively to obey in flight may be condensed into the following:—

1. Power only to counteract gravitation.

- 2. All bodies must be heavier than air.

  3. Acceleration of fall should never commence.
- 4. The body must be propelled from every direction but one.
  - 5. All elevators must act as levers.
- 6. The greatest available surface shall be parallel with and the least perpendicularly to the direction of flight.

In place of the existing two wings and fourteen aeroplanes, it is now proposed to construct a machine with two propellers on each side, working at right angles, and separated by a set of superposed planes. To drive these propellers, I employ two cylinders 15in. diameter by 5ft. stroke high pressure, exhaust steam, condensed with injector. no gearings or pumps, wings feathered direct from the main shaft within the shell, a shifting crank in place of eccentric, and the shell made independent of the main frame. The bearing surfaces are thereby reduced to one-half the original. The boilers, which are constructed from the most approved designs, expose 5,000 square feet heating surface to the flame of the hydrocarbon surface, converting, on average, 18lb. of water per 1lb. fuel into steam. The engines and boilers are placed in separate cars. The proposed working pressure is from 50lb. to 120lb. per square inch. Taking 100lb. as the highest, and the piston surface at 176 square inches of the travel, at 1,000ft. per minute, the power indicated would be  $(176 \times 2) \frac{100 \cdot 1.000}{33.000} = 1,060$ -horse power. With,

proportion to speed, a powerful forward impetus is the result. The same also applies to the downstroke. On the other hand, it has been proved that the downstroke is an elevating and sustaining power, whilst the upstroke is really the most powerful propeller, counteracting any excess of an upward motion produced by the downstroke. This control must, of course, depend on the amount of angle given; in short, the downstroke must elevate and propel, and the upstroke must govern and propel. Employing one wing only, as in the bird, we are placed at a disadvantage, inasmuch as we expend an enormous power on each upstroke, which increases with the speed. For example, take each wing as 50ft. from the base to the exposing an effective minimum surface of 2000 square feet, weighing 250lb. each. The centre of gravity being 20ft. from the base, and the power 2ft. from the fulcrum, hence  $\frac{22\text{ft} \cdot 250}{23\cdot 1000} = \frac{22\cdot 1000}{23\cdot 1000}$ 33.000

× 2 = 26½-horse power, 160 representing the travelling feet. Such a dead loss must be saved, but this can only be accomplished in the manner already described, having the aeroplane fixed with sufficient clear space in such a manner that they recoive the double effect of the current of air forced and drawn aft. We now wish to find where we obtain the pressure necessary to raise the machine. Although this is meant to run along the ground and gain a momentum, yet it is on the instant of rising that the greatest strain is thrown upon the engine. Let us take the performance of each wing at 100 strokes per minute, and the load which each has to carry at 4,500lb., the greatest rise at 40ft. = 8,000ft. per minute; the amount of leverage here required is equal to 200lb., but this lever is of great width, and, therefore, the pressure on 2ft. square is equal to (8,000ft. per minute = 133ft. per second =  $\frac{133 \cdot 133}{440}$ ) 40lb. per square feet ×

4,000lb. leverage. But I find from experi-50ft. ments that the wing on passing the horizontal line in its descent indicates on 64 square inches the same pressure which was calculated on 1 square foot when stationary. If, therefore, we take the sustaining pressure on an average of 10lb., we should have 450 times 10 = 4,500lb. on each wing = 18,000lb.; the power of the lever is here not called into question. The acroplanes are 50ft. long by 5½ft. wide, in sets of three, exposing a surface of 3,300 square feet. Allowing the minimum pressure of 4lb. per square foot, would equal 13,200lb., giving the grand total of 31,200lb. = 14 tons sustaining power.

You will perhaps remark that this result is the very extreme. I am ready to meet your argument, and deduct 2-3rds of this results, and then I shall have 10,500lb. of sustaining power. The wings being balanced, I find that the power required to keep the machine in motion when once in the air is 18,000lb. raised 120ft. high per minute. But with one pair of wings, nearly double the power is required. On the other hand, to start immediately upwards from the ground, the following work has to be done,—18,000lb. raised 33ft. high per second. But to avoid this enormous strain, it is compulsory that the machine be made to attain a certain velocity on the earth before rising. The law of progress in the air is, I believe, as the length of the wing multiplied by the travel in feet per second, divided by the angle plus the resistance in each square feet. The engine, as calculated, is capable of towing ten carriages (each sustained by its own sustainers), with a full complement of water, fuel, passengers, and goods at a considerable speed.

My paper has now been long enough to wear out your patience. I will, therefore, conclude, firmly believing (if properly operated) in the impossibility

The Chairman said that he understood that Kaufmann intended to make a machine of working dimensions, though not of largest power, and he gathered from his concluding remarks that it could not fail. He could only say that he hoped Mr. Kaufmann was right in that conclusion; but he (the Chairman) was so old now that he could not believe anything unless he saw it. All he could say was, that he had some little confidence in Mr. Kaufmann; still, seeing is believing with an aerial machine.

Mr. Olrick remarked that for the power proposed this machine is to have a cylinder 15in. diameter and of 5ft. stroke, to make 200 revolutions a minute, and would require a steam presmost efficient boiler is that called the Field boiler, and it would take one of eight or ten tons. He must see the machine sustain so heavy a weight before he believed it.

Mr. Quatermain said he had tried experiments with steam, and he had given it up. They must have gunpowder or something else.

Mr. Kaufmann, in reply to Mr. Olrick, said his machine could lift 29,000lb. He asked how much

power Mr. Stringfellow's engine developed?

Mr. Brearey: 1-horse power, weight 1611b. Mr. Kaufmann saw that Mr. Olrick had taken it for granted that the machine would have to take water with it, or else it could not go. Now, he did not propose to waste steam, but to economise it by use of a new injector and a condenser. would not require to carry water in the machine, but would distribute it over the ten cars that accompanied the machine. The oil for fuel would also be distributed over the ten cars. The amount of water would be comparatively nothing to the weight of boiler.

Mr. Olrick would ask how the horse power of Mr. Stringfellow's engine at the Crystal Palace was measured? The engine was so small that an ordinary indicator could not be applied to measure it. With regard to the condenser mentioned by by Mr. Kaufmann, he had omitted one great stumbling block—he must have fresh cold water, or the condenser would not work. The figures he had given related to one hour's work. Of course, for a number of minutes there would be less in proportion, and he had only spoken of the lightest boilers he knew.

The Chairman said he was convinced that the practical remarks made would be thought well of by Mr. Kaufmann before he proceeded with making his machine. With their thanks, however, they would give him their best wishes.

(To be concluded in our next.)

# Megal Intelligence.

VICE-CHANCELLOR'S COURT. May 27.

(Before Vice-Chancellor SIR R. MALINS.)

PULVERMACHER v. HAMMOND. Mr. GLASSE, Q.C., and Mr. T. A. Roberts moved in this case to restrain the defendants, Charles Daniel Hammond and Alfred Burrows, otherwise Henry James, from an alleged infringement of the plaintiff's patent for electric belts and galvanic magneto-electric apparatus, &c., and from pirating the plainelectric apparatus, &c., and from pirating the plain-tiff's trade mark, consisting of the words "Electri-city is life," variously advertised, sometimes in blue clouds with gilt lightning surrounding it, on an illuminated sheet. The plaintiff, Isaac Louis Pulvermacher, alleged that he had for twenty-two years past devoted himself to the study of electricity, galvanism, and magnetism, for alleviating bodily ailments, and carried on business at 200 Regent-street, and in Paris; that he had invented certain means of applying electricity by voltaic chain batteries and flexible bands and belts, and from 1849 to 1861 applied for and obtained patents for the same. The bill referred to these patents, and that he had submitted his invention to Sir Charles Locock, Sir H. Holland, Sir W. Fergusson, Sir J. R. Martin, and Drs. Sieveking, Quain, Clark, and Jones, from whom he received testimonials; and letters from Sir J. R. Martin and Sir Charles Locock were produced. The plaintiff then alleged that his system and inventions had met with great success, and that the defendants had for some years past carried on business at 11, Charlotte-street, Bedfordsquare, otherwise called Percy-house, in order to make it appear that they practised at different places. The bill then set out advertisements issued by the plaintiff and defendants, in some of the latter, the words "Electricity is life, by means of the patent electric belts," commencing them, and Dr. Hammond was stated as the inventor and patentee of scientific inventions, and James was stated, in one of the pamphlets which they had published, to be the doctor's confidential assistant. The defendant Hammond had filed a provisional specification for improvements in apparatus for the relief of bodily ailments; but that had been determined, and it was clear that there was no patentee but the plaintiff. There were affidavits by Sir Charles Locock, Sir Ronald Martin, &c. An affidavit of the defen-(176×2)  $\frac{10071,000}{33,000} = 1,060$ -horse power. With, however, the usual pressure of 50lb, the proportion will be as 1-horse power to every 19lb, dead weight. In examining the action of the wing, we find that, if the upstroke be properly feathered in

This had not been objected to by the plaintiff. Dr.

Hammond was out of this jurisdiction.
Mr. Cotton, Q.C., and Mr. Graham Hastings appeared for the defendants.

At this stage of the motion.

Mr. Glasse, Q.C., admitted that on that evidence he could not insist upon the interlocutory injunction.

The Vice-Chancellor said he was very sorry that the public could not be protected; for poor people in this country, seeing these advertisements, thought they could get cured. He had a strong opinion against the defendants on their own affidavits. The motion must stand over till the hearing.

### COURT OF COMMON PLEAS.

June 1. (Sittings at Nisi Prius, in Middlesex, before Mr JUSTICE KEATING and a Common Jury.)

READ v. NORRIS.

THIS was an action to recover damages for injuries suffered in consequence of the explosion of a boiler.

Mr. Folkard appeared for the plaintiff, and Mr. Shaw and Mr. F. Turner for the defendant.

The plaintiff was a turner, and the defendant was the proprietor of a saw mill in the Waterlooroad. In August last the plaintiff rented of the defendant some steam power, and on October 30 the boiler burst and two men were killed. The plaintiff's arm was very severely scalded, so that he had been incapacitated from work almost down to the present time, and beyond this he had lost the best part of his tools. The plaintiff's case was that the boiler burst through the negligence of the defendant. That the boiler was one upwards of thirty years old, that it had been made for a low pressure boiler, but that it had been worked by the defendant up to a pressure of 55lb. and 60lb. pressure per square inch. Further, it was said that some of the fittings of the boiler were not such as they should have been, and that the defendant had been warned that if he worked at such a high pressure there would be an accident.

For the defendant this last statement was denied. It was said that the fittings of the boiler were good; and, further, that before the boiler came into defendant's possession it had frequently been worked at 60lb. pressure and upwards, and that this pressure it was well qualified to bear. The cause of the explosion was that the boiler was mended in August, and, contrary to the defendant's direction, the work was ill done, and that the plate used was not of good material. As to the amount of pressure indicated shortly before the accident, there was conflicting evidence. The evidence for the plaintiff was that the pressure was 58lb.; whilst that of the defendant was that it was 48lb.

The jury, after hearing a good deal of evidence expressed their opinion that there was no negli-gence on the part of the person who repaired the boiler; and they found a verdict for the plaintiff -damages, £80.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 is. 8d, yearly, or 10s. 10d. half-yearly payable in advance.

advance.
All literary communications should be addressed to the Editor of the MECHANICS MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS MAGAZINE Office, 166, Fleet-street, London.
To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday ovening.
We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.
Advertisements are inserted in the MECHANICS MAGAZINE, at the rate of 6d, per line, or 5d, per line for 13 inser-

SINE, at the rate of 6d. per line, or 5d. per line for 13 inser-tions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate es type. Special arrangements made for large advertise

ments.

IF Mr. C. PEMBERTON, R.N., whose method of rifling smooth-bore guns we described and illustrated in the MECHANICS' MAGAZINE for the 14th May last, will send his address, we will forward him a letter which has been sent to our care.

Oulture," at 3 p.m.

### Rabal, Military, and Gunnery Items

THE United States' Government has determined to change its coaling station for naval vessels in the West Indies from St. Thomas to Samana Bay, owing to the high charges for coal made by the authorities at the former place.

THE President of the United States has awarded gold watch to Captain James Brown, of the brig Arrow," of Brixham, in acknowledgment of the services rendered by him in rescuing the master and crew of the American ship "Yarmouth," of Maine, wrecked in the Bay of Biscay in the mouth of March

Mr. E. J. Reed, C.B., was presented to the Prince of Wales at the levee on Tuesday last, on being nominated a Companion of the Order of the Bath, by the First Lord of the Admiralty. The presentations at that levee were, by the Queen's pleasure, considered as equivalent to presentations to Her Majesty.

REAR-ADMIRAL ASTLEY COOPER KEY, C.B., F.R.S., who commanded in chief the Reserve Fleet during who commanded in cline the Reserve Freet during its recent cruise, has been selected by the Admiralty for the appointment of Admiral Superintendent of Portsmouth dockyard, as successor to Rear-Admiral George Greville Wellesley, C.B., who vacates the office, it is understood, for another appointment.

On Tuesday week, a drummer was examining a Snider rifle, belonging to one of the Grenadier Guards, in the infantry barracks at Windsor, and trying to fit it with one of the Henry-Martini cartridges, when the cartridge slid down the barrel, the muzzle of which was held downward. Newell elevated the muzzle to check the progress of the cartridge, and the latter slid back and exploded with the concussion against the breech. The bullet struck the ceiling and rebounded, wounding a soldier on the tenule. and rebounded, wounding a soldier on the temple.

and rebounded, wounding a soldier on the temple.

The church which was erected in Woolwich Dockyard, for the service of the Royal Navy and Royal Marines, has been transferred over to the War Department. A portion of the building is to be set apart for the crew of H.M.S. "Fisgard," Captain J. M. Jackson, bearing the flag of Commodore Superintendent Edmonstone, C.B. On the closing of the dockyard, it is said that the "Fisgard" will be retained at Woolwich, and used as a receiving ship, being moored in the river not very far from her present position.

sent position.

Mr. James Hall, the senior partner of the famous firm of Hall and Sons, shipbuilders, Aberdeen, died suddenly on Saturday morning, while aiding at the extinction of a fire in a neighbour's wood-yard. The deceased gentleman who was in his 65th year, was the 'author of the now celebrated "clipper" model for ships, and his firm have long held a proud supremacy for the beauty of build and sailing power of their vessels. It has been said, that there is not a port in the civilized world, where "Hall's clippers" are not known. By this death, Aberdeen loses one of the worthiest and most eminent of her sons, while in the wide circle of British commerce, Mr. Hall was esteemed for his business qualifications, and for being steemed for his business qualifications, and for being a thorough man of his word.

THE death is announced of Captain Scobell, of The death is announced of Captain Scoboll, of Kingwell, Somerset, and formerly M.P. for Bath. He was born in 1785, and entered the navy when only twelve years of age. He served at first on the coast of North America, and, subsequently, in the coast of North America, and, subsequently, in the expedition to Copenhagen, under Sir Hyde Parker and Lord Nelson, in the blockade of Cadiz, and in the Channel fleet. He was made lieutenant in 1804, and commander in 1812. In 1823, Captain Scobell invented and submitted to the Admiralty, a "dissecting paddle wheel," to be worked by winches applicable to men-of-war of every size. These wheels were fitted to the "Hecla" and "Fury," in Sir William Parry's expedition to the North Pole, and with only twenty men at the winches produced a with only twenty men at the winches produced a speed of a knot and a-half an hour.

on Monday last an interesting and important operation was performed on board the Bermuda floating dock at Sheerness. It was the careening of the dock by the admission of 5,000 tons of water into the chambers of the port side, by which an angle of inclination to the extent of 47deg. was obtained. It caused the keel of the dock to emerge obtained. It caused the keel of the dock to emerge several feet above the surface of the creek in which she is moored. The object in view was to remove from the bottom an accumulation of grass and small barnacles, as well as to effect some necessary repairs within two feet of her keel. The latter was the more important part of the work, as the Bermuda is the only floating dock capable of being repaired by her own appliances. The injection of the 5,000 tons of water was commenced at half-past 9 a.m., and finished at injection of the 5,000 tons of water was commenced at half-past 9 a.m., and finished at half-past 1 p.m.; the discharge occupying only two hours. The operation, as well as the necessary cleansing, was performed under the direction and superintendence of Mr. Barnaby, the Admiralty overseer; and as a proof of the extraordinary buoyancy of the dock, he states that an additional 2,000 tons could have been suspended on the submerged side without endangering its safety.

LLOYD's Statistical Committee have just issued their annual statement of the number of their annual statement of the number of shipwrecks and casualties reported during the year 1868, together with the average and comparative percentage of the two previous years. From these, it is satisfactory to observe the practical benefit now resulting from the operation of the Act of 1865, establishing compulsory proof of cables and anchors. It appears the average casualties arising from default of anchors and cables in 1866 and 1867 numbered 748, as against 417 only in 1868. In 1866 and 1867, the average annual loss of life is stated at 1,995, while in 1868 the total was reduced to 1.118. a saving of 877; and this, notor the 18 stated at 1,393, while in 1868 the total was reduced to 1,118, a saving of 877; and this, not-withstanding the unusually severe and tempestuous character of the weather, as evidenced by the greatly increased number of ships dismasted in 1868 over former vears.

former years.

LAST Wednesday the first sod for the new docks at Fleetwood was cut. Fleetwoed is quite a modern town, possessing good marine and railway facilities, but it has never made that headway which its founders anticipated, and one of the principal causes of its slow progress is said to have been its lack of dock accommodation. This defect, is, however, about to be remedied, and when actually removed it is confidently expected that its shipping trade will be greatly improved and that the town and district generally will be greatly benefited. The new docks will cost about £50,000. They will be 600ft long, 400ft, wide, and be 23ft, deep outside at high water during an ordinary spring tide. Mr. Cox is the engineer, and Mr. C. Chambers the contractor.

MESSES, CAIRD AND Co., of Greenock, have

MESSRS. CAIRD AND Co., of Greenock, have contracted to build a steamer of about 3,500 tons burden for the Peninsular and Oriental Steam Navigation Company. Messrs. Henderson, Colborn, and Co., of Renfrew, have launched an iron screw of 900 tons burden builders' measurement. Her engines 900 tons burdon builders' measurement. Her engines are supplied by the same firm, and are of 120-horse power nominal. The steamer, which has been named the "Helge," has been built for Danish owners. Mossrs. Aitken and Mansel, of Whiteinch, have launched the "Breadalbane," a screw of 1,300 tons register. The "Breadalbane" will be fitted with combined high and low pressure engines of 150-horse power nominal by Messrs. T. Aitken and Co., of Cranstonhill,

WE learn that the Admiralty have now offered, WE learn that the Admiralty have now offered, and the Ship Committee, acting on behalf of the Tay Training Ship Institution, after careful inspection, have accepted as a training ship for the Tay, the "Mars," now lying at Sheerness. This vessel is upwards of 2,570 tons register, and with only 250 tons of ballast she draws 20ft. of water. She was originally built as an 80-gun line-of-battle ship: She was then converted into a screw of 400-horse power, carrying 68 heavy guns. She has been lying in ordinary as one of the steam reserve for the last seven years, but has lately had her engines and in ordinary as one of the steam reserve for the last seven years, but has Intely had her engines and boilers taken out of her. She is reported to be a good sound ship, with her hull in good condition, but, in consequence of being so long out of commission, and not having masts or rigging of any kind, and many new fittings being required, a considerably larger sum of money than was at first suitigated larger sum of money than was at first anticipated larger sum of money than was at first anticipated will be needed for her equipment. As the original estimate of expense will be exceeded, it is hoped that subscriptions will flow in on a more extended scale, so that the committee may not be hampered by want of funds.

### Miscellanea.

THE Council of the Society of Arts have arranged for a conversazione at the South Kensington Museum, on Wednesday evening, June 23.

It is computed that the total number of persons annually employed in getting coal in Europe is 700,000. In Great Britain, 300,000; in Belgium and France, 120,000; in Prussia, 80,000, and the remaining 200,000 elsewhere.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending May 29, was 3,828. Total number since the opening of the Museum, free daily (May 12, 1858), 1.578.766.

FORTY mines in the White Pine (Nevada) district are named after General Grant, and nearly an equal number bear Sheridan's name in various forms. Morning Stars, Evening Stars, North Stars, and all sorts of fanciful appellations abound.

LARGE premises have been fitted up in Victoria for the manufacture of colonial safes, which are actually stated, by a colonial paper, to be superior to those of English make. There is a large demand for them in the colony, and it is said they can be made 20 per cent. cheaper than the English article.

THE celebrated clock at Strasbourg is said to be put into the shade by that now exhibiting in Paris for the Cathedral of Beauvais. To hide a defect in the United the inhabitants decided upon having a monster clock. They subscribed 40,000 francs, and for the last four years ten clockmakers and twenty assistants have been at work.

THE completion of the Central Pacific Railroad was celebrated characteristically at San Francisco. When the telegraph announced the last rail laid, the whistles of thirty locomotives, gaily decked, and drawn up in line, screeched out in concert as an expression of joy, and all the steam whistles in the city joined in city joined in.

An exhibition of Turkistan natural and industrial products was opened a short time ago at St. Petersburg, but contains little that is new beyond a tolerably complete collection of mineralogical specimens. country contains abundant coal fields, and has also iron, the quantity and quality of which does not seem as yet to have been sufficiently investigated.

THE members of the Society of Engineers will visit the Limehouse Basin Improvement Works, and the West India Docks Extension Works, on June 4, this day. They will meet at the Railway Station, Stepney, at half-past 11 o'clock. The visit to the Limehouse Works is fixed for 12 o'clock, and the visit to the West India Docks for 2 o'clock, p.m.

The village of Oldbury-on-Severn is proverbially noted for the size and excellence of its salmon, but for this season at present, and for a half century past, the palm must certainly be awarded to Mr. George Highnam, who this day week caught a monster salmon of the following extraordinary dimensions:—Length, 4ft. 8in.; girth, 2ft. in.; weight, 43lb. The fish was very bright in appearance, and capitally grown.

UP to May 31 there have been 69 applications for Up to May 31 there have been 69 applications for provisional protections for patents made in this country this year, for improvements in the bicycle or two-wheeled velocipedes. We are not in a position to prophecy how many of them will becompleted for the first term of three years, but we anticipate great work for the law courts to settle as to who did or who did not invent the so-called improvements. inventions must clash more or less with one another

THE number of visicors to the South Kensington THE number of visions to the South Kensington Museum during the week ending May 29, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 13,372; Meyrick and other galleries, 2,388; on Wednesday, Thursday, and Friday (admission 6d.) from 10 a.m. till 6 p.m., 2,285; Meyrick and other galleries, 179; total, 18,224. Average of corresponding week in former years, 13,871. Total from opening of Museum, 8,483,428. 8,483,428.

THE quantity of gold received by escort at the Sydney Mint from the gold-fields of New South Wales in the first two months of this year was 34,480z., as compared with 40,2230z., in the corresponding period of 1868, showing a decrease this year of 5,7750z. The decrease appears to be general, but the largest diminution has occurred in the returns from the southern districts; the effects of drought had been felt most severely.

A LARGE room has been discovered at Herculaneum which must have served for a kitchen. In it was a wooden clothes-press, entirely carbonized; also fourteen vases, a candelabrum and a lamp, all in bronze, several vessels in glass and terra-cotta; a small marble statue of a faun, and two broken tables, one in marble and the other in slate. These excavations are carried on by means of the grant of £1,200, by King Victor Emmanuel, made for that object.

NEAR Boston, on May 11, there was a race between a velocipedist on the "bicycle" and a trotting horse, the "John Stewart." The horse was to go 10 miles while the velocipedist rode 5. The latter won the race, completing his 5 miles in 26min. 20sec., while the horse trotted 10 miles in 26min. 35sec. The best mile for the velocipedist was done in 4min. 29sec., and for the horse in 2min. 27 sec.

THE usefulness of small birds as destroyers of insects is thoroughly recognized by the Saxon Government, as is shown by a curious scene witnessed last week on the market-place at Dresden. A body of police suddenly made their appearance, and, without any previous warning, seized all the cages containing singing birds exposed for sale and released their inmates. A decree has also been issued forbidding, under penalty of a fine, the killing or trapping of these useful songsters, and containing especially severe regulations with regard to birdnessing.

THE removal of the India Museum from Fife THE removal of the India Museum from Fifed house to the new India-office having been completed, after much labour and time, it is now re-opened for public inspection. The museum was founded in 1798 by Mr., afterwards Sir Charles, Wilkins, at the old East India-house, Leadenhall-street, and when that building was vacated, the collection of Indian manufactures and produce was removed to Fifehouse, and remained there until 1867, when the palace of the new India-office was finished.

THE New York Legislature at the Session just closed provided for the creation of a monster railway corporation, with a capital of 150,000,000 dollars, by the consolidation into one company of what are known as the "Vanderbilt roads," those owned and controlled by Cornelius Vanderbilt and his friends. These are the New York Central, the Hudson River

the Haslam Railway, the Buffalo and Erie, the Lake Shore, and the Michagan Southern, forming a leading route from New York to the West.

THERE is no other spoken language so cheap and THERE is no other spoken language so cheap and expressive by telegraph as the English. So the electric wires are becoming teachers of our mother tongue in foreign countries. The same amount of information can be transmitted in fewer English words than French, German, Italian, or any other European language. In Germany and Holland especially, it is coming to be a common thing to see telegrams in English to save expense and ensure precision.

The Academy of Sciences, after a careful examination of the question, has determined, by a majority of 53 to 1, that the Astronomical Observatory shall be removed from the site which it has so long occupied, at the end of the gardens of the Luxembourg, and placed within a large enclosed space of ground without, but near to the limits of the city, in order to secure the astronomers from the inconveniences caused by the neighbouring buildings, railways, roads, &c. The working of the observatory is to be entirely independent of the new one for meteorological observations, which is now being erected on Montrouge, but both will be under the direction of the Minister of Public Instruction. THE Academy of Sciences, after a careful examina

There are in Holland about 36 soap manufactories viz., two at Breda, each producing annually 10,000 kilos. of hard soap, and 200,000 of soft or green soap; four at Amsterdam, producing yearly 121,000 kilos. of hard and 1,000,000 kilos. of soft soap; one at Enkhinzen, producing 50,000 kilos. of soft soap; and one at Hoorn, producing 109,000 kilos. of soft soap. At Amsterdam there is a eandle factory which ships annually 12,000,000 of candles, 300,000 kilos. of oleine, and 60,000 kilos. of glycerine. It works night and day, employing 200 workmen, and makes only for shipment. It has four boilers and steam engines of 111-horse power, four distilling apparatus, and many hydraulic presses.

Dr. Richardson has been conducting a series of THERE are in Holland about 36 soap manufactories

Dr. Richardson has been conducting a series of experiments with the huge induction coil at the Polytechnic. He finds that the spark from the coil itself, which measures 29in, in length, has no injurious effect when directed against a living body. A pigeon was experimented upon, having been first put to sleep by bichloride of methylene. It was connected by the foot with the negative pole of the coil, and one or two discharges sent through the body. There was a general muscular contraction at coil, and one or two discharges sent through the body. There was a general muscular contraction at each discharge, but the heart's action and the respiration remained perfectly healthy. In fact, the bird was perfectly uninjured, save as to the feathers which, strange to say, were somewhat singed. A tond also passed the same course with satisfactory results. The escape of the animals in these cases is due to the ready course of the current over their bodies. In fact, the body internally is not traversed by the current at all, but is surrounded by it. by the current at all, but is surrounded by it.

# Patents for Jubentions.

#### ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chromologic al order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

8466 A. TURNER, Leicester. Elastic fabrics. Dated No-

The object is to weave the fabric in such a manner that the silk may be made to cover the cotton weft at the selvage of the fabric, and thus present the appearance of a

silk selvage instead of a cotton one, as heretofore. This is effected by drawing off a somewhat longer length of silk than of cotton weft, by causing the silk weft to pass round the selvage wire when it is raised higher or dropped lower than when the cotton weft thread passes round it.—Patent abandoned.

—Patent abandoned.

3467 W. RICHARDSON, Oldham. Carding engines. Dated November 14, 1868.

The inventor dispenses with the usual card or other roller used for dofflug, and applies a reciprocating comb in conjunction with a roller, grooved at right angles to its axis. This comb removes the material and delivers it to the grooved roller, which then retains it in separate slivers.—Patent completed.

slivers.—Patent completed.

3468 J. Howard and E. T. Bousfield, Tubular bollers.
Dated November 14, 1868.

This relates to a patent, dated February 8, 1868, No. 430, the objects being, first, to facilitate the removal from such boilers of the scum that is thrown up by the impure water employed in certain localities: secondly, to improve the connections between the vertical and horizontal tubes composing the boiler; and, thirdly, to facilitate the deachment and removal of any one or more of the vertical tubes when required.—Patent completed.

the ment and removal any one or more of the vertical tubes when required.—Patent completed.

3469 C. K. Bradford, Lynnfield, U.S.A. Felocipedes
Dated November 14, 1868.

This consists, first, in the employment of a compound crank shaft—that is, of a shaft composed of or provided with two or more cranks of different lengths, the larger of which is to be employed in ascending an inclined plane or grade, and when more power and less speed is desired; and the smaller to be brought into use when the vehicle is traversing a comparatively level and smooth plane and a greater rate of speed is desirable and a less amount of power is required. The invention further consists in a novel employment of a rope or chain for steering the vehicle, and its application directly, or nearly so, to the axis of revolution of the third or "steering" wheel of the vehicle, by means of which much more direct and powerful control is had over this wheel than would be the case were this power applied, as is now generally the case, at a greater or less distance from such axis.—Patent completed.

were this power applied, as is now generally the case, at a greater or less distance from such axis.—Patent completed.

3470 J. C. M'DONALD and J. CALVERLET, Croydon. Stereotype printing. Dated November 14, 1868.

The object of the first part of this invention is to facilitate the casting of semi-cylindrical stereotype plates, and refers to a former patent, dated December 6, 1866, No. 3222. The core is now formed with grooves around its circumference, and the mould arranged so that the core may be lifted out in a direction at right angles to its axis. The invention, secondly, relates to giving a continuous and even supply of ink to the inking rollers of printing machines. For this purpose, in place of transferring the supply of ink from the feeding roller (which revolves slowly in a trough containing the supply of ink to the first of the distributing rollers (which travel at the same surface speed as the type surface), by means of a roller vibrating to and fro, so as alternately to come into contact with the two rollers, as herotofore. Thirdly, to holding the roll of paper in that class of printing machines in which the paper is drawn continuously through the machine from a roll. The inventors fix the roll of paper on a spindle, which passes through the roll, and which is formed so that it may then be expanded and caused to fit tightly in the hole through the roll of paper. For this purpose the portion of the spindle which passes through the roll of paper is divided longitudinally into two wedge-formed pieces carry at their ends one of the axes upon which the spindle and roll are to rotate. When the two halves of the spindles have been introduced into the roll of paper, they are caused to separate one from the other by smaller wedges, which are embedded in recesses in the inclined faces of the two halves of the spindle heigh moved endwise by screwa, and so caused to stand up above the faces in which they were previously embedded.—Patent completed.

3471 H. Aitken, Falkirk, N.B. Treating tron ores. Dated Novembe

Dated November 14, 1868.
The iron ores or ironstones are placed in any convenient kind of retort, kiln, oven, or chamber, made as air-tight as possible, which may be placed vertically, horizontally, or at any angle, and a fire is placed so as to act in the retort, kiln, oven, or chamber, which is so constructed that no air is admitted without having first passed through the fire, so as to consume the oxygen that is in the air—Patent completed.

—Patent completed.

3472 J. H. Johnson, Lincoln's Inn. Railway wheels. (A communication). Dated November 14, 1868.

This consists in arranging strengthening ribs within the hollow rim, and in making the flanged side of the rim straight or nearly so, and at right angles or thereabouts, to the internal strengthening ribs above referred to, the objects of this part of the invention being, first, the affording facilities for easily casting the hollow rim with its internal ribs. The invention also consists in a cast-iron railway wheel, in which the nub and rim are connected together, partly by two concavo-convex plates, and partly by a single plate or web, forming a continuation of the said concavo-convex plates from the point where the two meet; also, of an annular rib made on the inner circumference of the rim, and forming a continuation towards the centre of the wheel of the flange, whereby greater strength is obtained. Strengthening ribs extend from the concavo-convex plates above referred to, and terminate at their outer ends, upon the annular rib before mentioned.—Patent completed.

3473 T. Berney, Beacon Hall. Ordsance and armous.

3473 T. Berney, Beacon Hall. Ordnance and armour Dated November 16, 1868.

This is partly based upon an invention, for which a patent was granted, dated January 25, 1867, No. 193, for improvements in constructing and applying defensive armour.—Patent abandoned.

3474 J. C. BOWLER, Hale. Castors. Dated November 16,

1868.

This relates, first, to that class of castors usually termed "ball castors," and the improvements consist in forming the interior portion of the cup or socket, against which the ball rests, of a swivel or movable curved plece, the remainder of the socket, containing the ball, being rather larger than the ball, which, when revolving, touches it on the side opposite to the direction of its motion, a little below the centre of the ball. The swivel or movable top bearing forms a resistance against the ball, in a direction hat adapts itself to the varying movements of the castors

Second, in adapting inclined movable surfaces as bearings coud, in adapting inclined movable surfaces as bearings, a first which the castors are secured; these inclined bear-gs are capable of being moved forward simultaneously, means of sciews.—Patent abandoned.

by means of sciews.—Patent abandoned.

3475 H. A. BONNEVILLE, Parls. Missiles. (A communication). Dated November 16, 1868.

The missile is of a conical-ogival conical truncated form, that is to say, it is composed of a point and body. The point is conical-ogival, and the body of the shape of a truncated cone, or of soveral parts of a truncated cone, or of soveral parts of a truncated cone joined together with the point. The missile is cast in a chill, and hardened outwardly, by plunging the gill into cold water, constantly renewed. If hollow, it has an inside chamber of iron or cast iron. The missile may be hardened inwardly, by causing a current of cold water to pass at high pressure through this chamber, thus rapidly cooling the yet liquid metal which has been poured into the chill.—Patent completed.

3476 J. SMITH, Chatham. Finishing fabrics. Dated No.

vember 16, 1863.

This consists in finishing woven fabrics, by passing them over and under a series of rollers, covered with card fillets or emery, or any other rough substance or perforated metallic rollers may be used. This coating or covering the rollers with card fillet or other rough surface is for the purpose of causing the fabric to adhere to the rollers, whilst an end to and fro motion is given to them by eccentrics on a side shaft or otherwise.—Patent abandoned.

3477 H. CARTER, Manchester. Gas burners. Dated No.

3477 H. CARTER, Manchester. Gas burners. Dated November 15, 1868.

The application of gas burners of the well-known "hydrocarbon" burner, and the improvements consist in supporting or attaching to one end of a balanced lever the "hydrocarbon" burner, which consists of a flattened piece of metal that is constructed to slide upon and fit the ordinary gas burner, so as to divide the flame opposite the end of the lever to which this piece of metal is attached. The latter is connected by a rod to an eccentric crank or other equivalent that is caused slowly to revolve through the medium of a coiled spring and wheels, similar to the works of a clock, the revolving of which transmit a rising and falling motion to the hydrocarbon burner, which, when in its lowest position, rests upon and divides the flame of the gas burner, and, when raised and free from the burner, leaves the flame of gas to burn in the ordinary manner.—Patent abandoned.

Patent abandoned.

3478 T. Martin, Dublin. Ammunition cases. Dated November 16, 1868.

These cars or trucks are constructed as follows:—They are formed with a watertight body provided with a lid or cover, also closing in a watertight manner, so that the car may be drawn through water without injury to its contents. The handle by which the car is drawn consists, by preference, of a pioneer's spade, of which the blade fits against the bottom of the car, while the handle is secured to the same by means of a clasp. At the back of the body as loop handle is provided, by which it can be lifted or pushed. A small watertight compartment is attached to the front of the body to hold gun, spikes, hammer, and mails, bandages, pins, lint, and other indispensable objects for succouring the wounded. One or more saws are fitted at the sides of the body, and pioneer's tools on the lid thereof, whereby the body will be rendered, to a certain extent, bullet proof. The car runs upon two wheels, which are, by preference, made of such a diameter as to be exactly 6ft. in circumference; and on the axle, which is fixed to and revolves with the wheels, is a worm, in gear with which is a worm wheel on the body of the car, imparting motion to any suitable known counting or registering mechanism.—Patent abandoned.

Imparting motion to any suitable known counting or registering mechanism.—Patent abandoned.

3479 J. J. RAVEL, Paris. Steam generator. Dated November 16, 1868.

This consists of a new arrangement of steam generator with rapid water circulation, heated by petroleum or mineral oil, by the aid of particular apparatus, and applicable to all industrial purposes, but more especially to steam locomotion on ordinary roads. The boiler is composed of a single serpentine coil (preferably of copper) communicating by its lower extremity with a double metallic envelope, and by its upper end with a steam reservoir, formed by an outer envelope of iron, steel, or copper. The water is fed in at the lower part of the double envelope by means of a feed pipe, and fills the same, and then enters the serpentine coil at its lower end, in which it rises and escapes from its upper end in the form of steam into the steam reservoir, which surrounds the whole apparatus. The furnace is placed below the serpentine, the coils of which are closed in such a manner as to form a wall all round. The gases of combustion are compelled to pass upwards through the cylindrical envelope thus formed, and then descend between the exterior of the spiral and the interior of the double envelope, and pass by a circular chamber, which surrounds the steam reservoir, to the chimney.—Patent completed.

3480 J. Matheson, jun., Glasgow. Dyeing and washing yarns. Dated November 16, 1868.

This consists in effecting these operations on the yarns by means of apparatus such as is at present used for dyeing and washing Turkey red cloth. The hanks of yarn are connected together to form chains by means of rings of brass, or other suitable material. The rings are made in any convenient way, so as to admit of easily connecting and disconnecting the hanks.—Patent abandoned.

3481 E. and A. Priest, Huddersfield. Carding engine.
Dated November 16, 1868.

The inventors apply a card roller mounted so as to rotate under and in contact with the first doffer cylinder at a slow speed, or such different surface speed to the doffer as will enable it to strip or take off the aforenamed bits of objectionable substances therefrom, and thereby prevent them passing forward through the machine along with the properly-carded fibre, an ordinary stripper being applied to work in connection with this roller, to knock off or remove the said bits therefrom.—Patent abandoned.

3482 E. Hogg, Gateshead. Straightening and planishing fron. Dated November 16, 1868.

This consists in the use of steel or chilled cast iron frictional rollers suited to the shape of iron required to be straightened and planished, such rollers being arranged so as to admit of the iron under operation being passed through them in a straight line. The pair of rollers in the centre of the machine are horizontal, and has a pair of vertical rollers placed one over the other at a suitable

distance on each side of the pair of central rollers. The horizontal central rollers are coupled by toothed wheels, one of which, on the vertical shaft of one of the said rollers, is driven by suitable gearing from the main shaft. The other roller is adjustable, as required, by means of a screw. The top vertical rollers are also adjustable.—Patent completed.

3483 J. HARE, Handsworth. Expanding tables. Dated

November 16, 1868.

This consists in making the screws used in table expanding apparatus or machines, by twisting or compressing the metal into the forms required to produce the threads, instead of cutting a portion away—Patent com-

threads, instead of cutting a portion away—Patent completed.

3484 A. M'NIEL and W. WHEATON, Exeter. Saits of ammonia. Dated November 16, 1868.

This relates to a process for obtaining sulphur saits of ammonia from ammoniacal liquor, more particularly that obtained in the manufacture of gas, the principal object being to obtain the ammonia in such a form and combination that it may be used as a manure. The inventors take the ammoniacal liquor as it comes from the gas works and add thereto a compound of earthy matters, of which gypsum or impure sulphate of lime (as obtained in the raw state) and chloride of sodium or common sait form principal ingredients; gypsum or sulphate of lime, when added to ammoniacal liquor, becomes decomposed, and the acid contained in the gypsum combines with a portion of the ammonia and forms sulphate of ammonia and hydro-sulphuret of ammonium, but it has been found that sulphate of lime alone will not be sufficient to take up or disengage all the ammonia contained in the liquor.—Patent completed.

3485 B. M. BONIWELL, Richmond, Surrey. Ricer boats.

forms sulphate of ammonia and hydro-sulphuret of lime alone will not be sufficient to take up or disengage all the ammonia contained in the liquor.—Patent completed.

3485 R. M. Boniwrli, Richmond, Surrey. River boats. This consists in two boats which are so nicely constructed in capacity and weight that their displacements are equal. These boats are held together by connecting braces. Nearly in the centre of these boats are constructed and fastened on to the deck of each, double bearings, through which revolves a crank shaft which has two cranks constructed thereon at 180deg. from each other. On each crank bearing there are two swivel links working on the crank at each end, and at the other end on the end of the treadles which work at the opposite end on two swivel links, which links swivel on the centre portion of the brace.—Patent completed.

3486 W. Low and G. Thomas, Cardiff. Suspension bridges. Dated November 16, 1868.

The inventors form the suspension chains for suspension bridges by combining together a number of oval link chains. These chains are placed side by side, and filling blocks or keys are driven in through the alternative corresponding links of the several chains, so as to bind them all together. They also combine several such compound chains by laying them one over the other, and driving filling blocks or keys through the several chains by the links which previously were left void.—Patent completed.

3487 S. W. CAMPAIN, Spalding. Steam tilling. Dated November 16, 1868.

The inventor provides the anchor carriage with a revolving anchor to restrain its forward motion. This anchor consists of an axis mounted on the carriage and having times or teeth projecting into the ground; on the axis there is a ratchet wheel, into the teeth of which a stop enters and holds the axis so long as it is not desired that the carriage should move forward, but when a forward movement is required, the stop is lifted by a hand lever, and then the anchor carriage are arranged so that they may be adjusted to project m

the strain which comes upon it.—Fatent completed.

3488 J. JONES and S. P. BIDDER, Mitcham. Breaking
doten coal. Dated November 17, 1868.

This consists in breaking down coal, slate, stone, and
other minerals, by means of apparatus wherein two or
more wedges are caused to be driven consecutively by
hydraulic or screw power between the surfaces of the substances to be broken down.—Patent completed.

stances to be broken down.—Patent completed.

3486 H. A. BONNEVILLE, Parlen tompleted.

3486 H. A. BONNEVILLE, Parlen Prognasticating the weather. (A communication). Dated November 17, 1868. The instrument is composed of the motor which imparts motion to the index needle. The motor is composed of two wooden strips or thin blades stuck one upon the other, the one operating the movement of attraction, which is called the positive, and the other operating the movement of repulsion, which is called the negative. These strips or thin blades of wood are curvilinear, and assume the form of an are of a circle. One of the extremities of this are is fixed to a square held by screws onto a brass disc; the other extremity is loose and movable; it is connected by a aliken thread passing round one of the two grooves of a pulley with an arbor forming the axis of the index needle. The attraction of the motor is counterbalanced by a spring fixed upon the brass disc and connected by another siken thread with the arbor, round the second groove of which it is wound.—Patent completed.

3490 R. Green, Rayswater. Covering telegraph wires.

completed.

3490 R. Green, Bayswater. Covering telegraph wires.
Dated November 17, 1868.

This consists in adapting and employing an exterior tubular covering or casing of suitable thickness and strength, which is proposed to be manufactured of lead or other soft or suitable metal, inside which covering or tube is enclosed or contained the telegraph wire or wires covered or surrounded with the ordinary insulating medium of india-rubber or other suitable insulating substance, the wires and insulating material fitting tightly inside the metallic covering or tube.—Patent abandoned.

3492 Gerard. Marquis de Montrichard, Paris. Trans-

density is used as counterweight to a column of quid of lighter density, sucked or supported in ultaneously, answering the purpose of a piston. completed.

completed.

3494 L. M. PREWETT. Stays. Dated November 17, 1868. This consists in the application to certain parts of stays or bodices of metal eyelets, formed with stamped heads, shells, or covers, and rings. or washers affixed thereto, which may be placed on the outside back and front, if required. The eyelets thus made are inserted through the material of the stays or bodice either at or through the ends of the ribs or bones of the same, which are usually formed of whalebone or steel, the shank or open end of the eyelet being secured in the ordinary manner.—Patent abandoned.

—Patent abandoned.

3495 W. R. Lake. Southampton-buildings. Bayonet. (A commulcation.) Dated November 17, 1868.

The handle of fire bayonet is made with provision for slipping it upon and locking it to the end of a musket or rifle barrel, and is united to the blade by a shank, the construction of the bandle and shank being the same, or substantially the same, as in the common bayonet. The blade is made trowel or spade-shaped, except that its body is preferably curved transversely the better to adapt it for use in retaining earth upon its surface, and it will be obvious that by bringing the front end to a point, the implement may be as readily used as an offensive as when made in the long slender form of the common bayonet.

—Patent completed.

—Patent completed.

3496 W. MANSFIELD, Birmingham. Brick sheds. Dated
November 17, 1868
This refers to such kilns as consist of a series of ovens
arranged in an annular form. The invention consists in
making the said annular space between the ovens and the
stack into a series of chambers, under which the flues of
the ovens pass, and heat the said chambers by the waste
heat from the ovens. The inventor employs these chambers
as drying sheds or drying chambers for drying the bricks
or other articles preparatory to burning. Entrance is
gained to said chambers or sheds either from the top
or by horizontal passages from the ovens.—Patent abandoned.

doned.

3497 A. CLARK, Chancery-lane. Making ginger snaps. (A communication). Dated November 17, 1868.

This consists in a box in which the dough is piaced, and which is securely attached to the frame of the machine. The dough has openings formed in its bottoms, through which the dough is pressed by the action of the follower, which fits into the dough box, and is securely attached to the lower ends of the bars, the upper ends of which are pivoted to the cross bar, so that the follower, when raised out of the box, may be conveniently swung to one side, to allow free access to the interior of the said box. In the ends of the cross bar are formed holes, having screw threads cut in them, through which pass the acrews, so that the follower may be raised and lowered, by turning the screws. The lower and upper ends of the acrews work in sockets or bearings attached to the frame.—Patent completed.

3498 H. A. Kehde, Kilburn. Working railway points.

S498 H. A. KEHDE, Kilburn. Working railway points. Dated November 17, 1869.

The inventor mounts a chain wheel or drum, so as to turn freely in bearings on a suitable framing or standards. A chain passes over this drum, one end being connected to the chain by rods, by which the signal, point, or switch, is operated, and to the other (which is pendent from the wheel) is attached a counter-balanced weight, for keeping the links or rods taut, and at the same time assist in maintaining the signal in position. On the axis of the chain wheel on either side he mounts an oscillating bell crank or other lever, the said levers being connected together at their extremities, and provided with pawls at one end, engaging with ratchet wheels formed on either side of the chain wheel, the said ratchets and pawls being arranged to act in contrary directions, so that on the bell crank lever being oscillated in either direction, the chain wheel will be partially rotated therewith, in order to raise or lower the signal as desired. The other extremities of these oscillating levers are connected to the ordinary hand lever, by which they are oscillated in either direction, for operating the signal or switch.—Patent abandoned.

3499 C. RICHARDSON, Gracechurch-steet, E.C. Looms.

3499 C. RICHARDSON, Gracechurch-steet, E.C. Looms.
Dated November 17, 1888.
This relates to improvements in looms for weaving, in which the shuttle is driven across the loom by a current of air acting directly upon each shuttle, and the invention mainly consists in certain improved arrangements and combinations of mechanism for effecting this object.—Patent completed. Patent completed.

3500 J. M. PRICHARD, Park-street, Hackney. Fountain Dated November 18, 1868

penholder. Dated November 18, 1868.

The barrel of this penholder, either in part or altogether serves as the ink reservoir, and all separate tubes or other apparatus inserted in or attached to the penholder, for holding the ink, are, therefore, dispensed with. The pen is attached to the penholder, in the method ordinarily employed when hollow penholders are used, by being inserted in a tube, whose opposite end is inserted into the barrel of the penholder, in such manner that it may be withdrawn at pleasure. This end of the tube is perforated with one or more holes to allow the ink to flow to the pen, or the end may be left entirely open for the purpose, the sides of tubes being made to it into the barrel in an airtight manner, by a coating of india-rubber or otherwise.—Patent abandoned.

2501 C. W. Sievens Great Georga streat. Finitesion.

Patent abandoned.

3501 C. W. Sirkens, Great George-street. Fusiening telegraph wires. Dated November 18, 1868.

The object of this invention is to provide a ready and simple means of attaching telegraphic line wires to insulators, whereby such wires may as readily be released again when required. For this purpose, the inventor constructs an eccentric or cam carried by a pin, upon which it can turn, and situated between two studs or grooves in such a manner that when the cam is turned into a certain position, the telegraphic line wire can pass freely between its edge and the studs or grooves, but when turned into another position, it is caused to press upon the portion of the wire between the two studs or grooves, and to bind it down, whereby the wire will be securely held. Instead of two studs or grooves, one only may be employed, and the wire be bent down on one side thereof by the eccentric or cam, or two such secentric or cams may be made to bend the wire down, one on each side of the stud or groove.—Patent sempleted.

3502 W. P. NASH, Great St. Helen-street. Postal boxes. (A communication). Dated November 18, 1868.

The inventor takes manilla hemp paper, or other strong or tough paper, and cuts the same into such a form or configuration that, when doubled up, a box can be formed of the same. Before forming the box, he so covers or partially covers the paper with tinfoil or lead, that the box when completed is lined with the tinfoil or lead.—Patent abandoned.

3503 C. E. BROOMAN, Fleet-street. Greasing wool. (A communication). Dated November 18, 1868.

This consists in an unctrous liquid product for oiling or greasing wool, silk, jute, and other textile materials. The base of this product is the common fucus (a kind of plant of the family of the ficoidal crytogames) collected in the form of grass on the sea coast, and from which the fatty part and the soda which it contains are extracted.—Patent abandoned.

3504 T. O. WARD, W. IBOTSON, and A. G. SOUTHBY few Inn, W.C. Manufacture of paper. Dated Novem-

abandoned.

3504 T. O. WARD, W. IBOTSON, and A. G. SOUTHBY, New Inn, W.C. Manufacture of paper. Dated November 18, 1868.

This consists, firstly, in evaporating alkaline liquor by means of the heat afforded by the regulated supply to and combustion in a suitable sole or fireplace, of the hydrocarbonaceous matter which such liquors hold in solution, the effect being to supersede, in a greater or less degree, partly or wholly, according to the less or greater dilution of the liquor, the necessity of coal, or other extraneous fuel for its desiccation. Secondly, in separating from the liquor under treatment to this end, either continuously or at intervals, as frequent as conveniently may be, its said self-contained fuel, so far as this solidifies to a crust or deposit coherent enough for removal. Thirdly, in applying this liquor-derived fuel in one or other of the following ways, viz, to feed a fire so disposed as to heat a series of three or more shallow liquor trays or receptacles, superposed in a chamber in such a manner that the heat may pass over and under them in succession, the first of such receptacles being fed by a regulated influx of the liquor for treatment, the second by a regulated supply from the first, and so on, each receiving a more concentrated supply till solidification commences, when the solid matter is removed from the liquid to a succeeding receptacle, where it undergoes further desiccation, and is finally advanced to the sole or fireplace in which it takes fire and is incinerated.—Patent completed.

advanced to the sole or fireplace in which it takes fire and is incinerated.—Patent completed.

3505 M. WILEIN and J. Chark, Paddington. Mining. Dated November 18, 1868.

The inventors propose to use lamps having gas, oil, or other illuminating materials, but instead of allowing these lamps to draw the air proper for their combustion from the surrounding air, they furnish them with air propelled from a pure source, such as the bottom or top of the shaft. They convey the air to supply the combustion in air-tight tubes to the interior of the lamps. They supply a greater quantity of air to the lamps than is necessary for the combustion of the gas or other illuminating material, and the overplus is caused to blow gently out of the escape valves or covers near the top of the lamps, thereby preventing the entrance of foul air, or air which has become mixed with inflammable gas in the mine known as firedamp.—Patent abandoned.

3506 A. M'DOUGALL, Manchester. Phosphatic manures. Dated November 18, 1868.

The inventor takes animal charcoal, or the substitute for animal charcoal, described below, and treats it with sulphuric acid, and then separates the sulphate of lime by filtration or other convenient means. He then agitates this sulphate of lime with ammoniacal liquor resulting from the destructive distillation of carbonaceous substances. By this means he obtains in solution sulphate of ammonia, which he separates from its solution by evaporation. The solution of acid phosphate of lime resulting from the destructive distillation of carbonaceous substances. By this means he obtains in solution sulphate of ammonia, which he separates from its solution by evaporation. The solution of acid phosphate of lime resulting from the destructive distillation of an evaluation of acid phosphate of immer as a substitute for animal charcoal in crystallizes as a substitute for animal charcoal in the above process by taking substances in a fine state of division containing phosphate of lime, and mixing with small coal or pitch, or other

vessels.—Patent completed.

3507 A. W. DRAYSON, Woolwich. Cooling wort. Dated November 18, 1868.

This relates to the cooling of liquids by employing the well-known principle of evaporation, which is induced or expedited by the aid of artificial currents of air to produce greater cold on the surface of the vessels containing the liquid to be cooled than the liquid indicates which is evaporated on those vessels. This result is obtained by alternately moistening and then drying the surface of the vessels containing the fluid to be cooled.—Patent completed.

pleted.

3508 B. Bell, Regent's Park. Iron ships. Dated November 18, 1868.

This consists, first, in increasing the depth of the hollows by the introduction of a strip of iron or other metal or material between each inside and outside plate, for the purpose of filling the enlarged hollows thus formed. Second, in filling these hollows with wood planking or other material, of such a thickness as to make the exterior of vessel a flush surface. The flush surface is then coated with sheets or plates of zinc or other metal sheathing, of such a breadth or size as to overlap and entirely cover the exterior iron plates, and the sheathing sheets or plates are fastened into the wood planking.

—Patent abandoned.

2509 W. L. GROUNDWATER. Plumstead. Cars and cart-

2510 W. T. Brown of the same.—Patent abandoned.

2501 W. T. Brown of the same.—Patent abandoned.

for recapping the same.—Patent abandoned.

3510 W. T. BASSET, Sydney, N.S.W. Dressing sheep.
Dated November 18, 1868.

The apparatus the inventor employs in carrying out this invention may be of a stationary character, or it may be so constructed and arranged as to be capable of being moved from place to place on land, in trucks or otherwise, as required, or it may be mounted on pontoons or otherwise arranged so as to be capable of being floated from place to place, and worked either on land or water. The

animal to be washed is taken, when either on land or in water, and secured, by preference when in the water to travelling bearers and yokes, and carried through the apparatus, and it is preferred to secure the animal to such travelling yokes when laid upon its back. Adjustable collers, clips, or other suitable contrivances are provided, attached to the travelling bearers, by means of which the neck or other part of the animal is held in the desired position, whilst being carried through the apparatus, and it is preferred to mount the travelling bearers and yokes upon an endless chains or ropes, though they may be otherwise mounted and actuated, according to this invention, such chains or ropes passing around chain or other wheels, to which movement is imparted by means of suitable driving wheels or pulleys, so as to cause the chains and bearers being under the control of an attendant, who either gives motion to such travelling chains, or has the mechanism by which they are actuated under entire command.—Patent completed.

chanism by which they are actuated under entire command.—Patent completed.

"8611 H. D. Hossold and G. P. Wheeler, Cinderford Gloucester. Artificial fuel. Dated November 19, 1868..

The inventors take small coal, coal dust, lime, coal slack, culm, or other bituminous substance, which they grind fine, and to this they add during the process of grinding "coal shale clay," and, by preference, make choice of that particular shale which is always found associated with coal of every kind under ground. This they intimately mix with the coal dust, slack, or culm, and pass the same into a mixing pan, when to the substance mixed they add pulverized resin, a proportion of asphalte or compact natural bitumen, to which a vegetable glue is added, made in the following manner:—To fifty gallons of water, the inventors add five pounds avoirdupois of rice, and five pounds avoirdupois of the glue or gluten extracted from Indian corn, meal, or miaze, which, when in solution boiled for half an hour, is fit for use. The above quantity is used with the above ingredients, and when thoroughly mixed together in the mixing pan, the whole is caused to adhere and form a compact paste, and can then be moulded into blocks, which is done by pressing machinery, and under such a pressure that the block will become solid. The paste thus moulded into blocks is placed in a drying chamber or vessel, in order to be desiccated, when it becomes, in a short time, so hard as to bear carriage to a considerable distance.—Patent completed.

3612 G. V. FOSBERRY and V. C. COWLEY. Breech-loaders.

3512 G. V. FOSBERRY and V. C. COWLEY. Breech

3612 G. V. Fosberry and V. C. Cowley. Breech-loaders.
Dated November 19, 1868
The block slides in vertical grooves in the breech chamber, and is raised or depressed therein by a lever pivoted at the rear of the chamber. The firing pin extends through the block and lever. The block and lever are depressed to open the breech, and the empty cartridge shell is ejected, and the plees cooked by one movement of a sliding extractor bar, which is arranged at the side of the breech chamber. A stud on this sliding bar works in an inclined slot or passage in the lever, and acts as a cam to raise or depress the same. The main spring is attached to the under side of the block lever, or when the lever itself forms the breech block of stopper, the spring may be fixed directly on the block. The lock is provided with a hammer, which, by means of an ordinary trigger, is caused to drive forward the firing pin. The block lever is sometimes provided with a plate, which is caused by the extractor bar to start the pin from the base of the shell.—Patent abandoned.

3513 S. CRIGHTON and J. TATT, Manchester. Grinding

extractor bar to start the pin from the base of the shell.—Patent abandoned.

3513 S. Crighton and J. Taft, Manchester. Grinding cards. Dated November 19, 1868.

The inventors arrange the grinding roller with its axis at right angles, with the line of direction of the traverse or at an angle therewith, other than a right angle in contration to the parallel or nearly parallel arrangement. The roller is caused to revolve on its axis, and at the same time, has a to and fro motion, in the direction, or nearly in the direction, or learly in the direction of its axis, and is also traversed from end to end of the flat or flats, or of the card rollers, liekers, or other roller or rollers, or cylinder or cylinders, being at the same time operated upon as will be well understood; or, if preferred, the roller flat or cylinder being operated upon may be traversed in the direction of its axis or of its length. The traverse is effected by means of a revolving scrow, fitted with an arrangement for reversing the direction of motion of the screw, when the grinding roller reaches each end or side of the surface being operated upon, one may be effected by other suitable or well known means, and the motion of the said grinding roller endwise is effected by means of eccentric or cam, sliding on a revolving shaft, or by other suitable means, the revolving motion being imparted to the said grinding roller by means of bevel gearing, or by means of a "flying band" or otherwise, as found most suitable.—Patent completed.

3514 W. THOMPSON, Dublin. Packing cases. Dated November 19, 1868.

This consists in so constructing cases or boxes for packing bottles or jars, that these are held securely in their places by means of springs of metal, india-rubber, or other material made to press against one or both ends thereof.—Patent completed.

Patent completed.

3515 C. D. ABEL, Chancery-lane. Phosphorus. (A communication). Dated November 19, 1868..

This consists, mainly, in the treatment of materials intended to produce phosphorus, directly in the presence of the fuel inside a blast furnace, in which the combustion is accelerated by the application of an air blast. This new application of blast furnaces in combination with blowing machinery, to the manufacture of phosphorus, constitutes the essential feature of this invention, the principal advantage of which consists in substituting for the laboratory apparatus employed heretofore for this purpose, an industrial apparatus, namely, the blast furnace, of simple construction and operation, thus really rendering the manufacture of phosphorus an industrial operations capable of boling carried on on a large scale. This apparatus may be employed with equal advantage for producing both varieties of phosphorus, namely, the ordinary phosphorus and the amorphous phosphorus.—Patent completed.

3516 H. Carrieg, Manchester. Tribasic phosphate of

amorphous paosphorus.—Patent completed.

3516 H. Carrigo, Manchester. Tribasic phosphate of lime. Dated November 19, 1868.

This consists in the manufacture or production of tribasic phosphate of lime from horn piths or solid bone or other osseous substances, by decomposing them in diluted hydrochloric acid, and afterwards precipitating the phosphate with slacked lime. The phosphate thus produced is used with great advantage for cupelling flint glass, making polishing plate and similar materials, and

also for phophatizing flour sweetmeats and similar articles. —Patent, abandoned.

—Patent abandoned.

3517 W. Avery and A. Fenton, Redditch. Needle cases.
Dated November 19, 1868.

The inventors form a quiver or flat case to receive a packet of needles, one end of the case being open for such purpose. At or near the bottom end of the case in one side they cut a slot in which works a thumb bit or small stud, attached to a clip or holder. Into this clip or holder the end of the needle packet is insorted, so that to expose or extract the needles, the thumb bit or stud is pressed and slides upward in the slot, taking up and partly out of the case the needle pakeet, which is pressed down into its place when required.—Patent completed.

3519 D. JONES and J. JACKSON. South Hackney. Heat-

the case the needle pakeet, which is pressed down into its place when required.—Patent completed.

3519 D. JONES and J. JACKSON, South Hackney. Heating the body. Dated November 19, 1869.

This consists in a box or chamber, which may be constructed either of any suitable form, so as to be portable or movable or a fixture, and formed of metal, wood, wickerwork, papier mache, or other suitable material, alone or combined with other materials. The sides or bottom, or both the sides and bottom, of the box or chamber are perforated or provided with apertures, which may be protected by wire gauze, or finely perforated metal, so as effectually to confine the flame of the lamp within the box or chamber, these perforations or spertures being for the admission of air to the interior of the box or chamber for the support of combustion, and the inventors prefer to provide the box or chamber with feet or supports to raise the bottom of the box or chamber a short distance above the floor or place upon which it may stand. Within the box or chamber they arrange a vessel containing oil or spirit, which it is preferred to be so arranged as to be readily removable, and they provide this vessel with one or more wicks, burners, or other contrivances for burning the fluid contained in the lamp or vessel. Ordinary burning oils or spirits may be employed for combustion in the lamp, but according to their improvements the inventors prefer to employ spirits of wine or methylated spirits, owing to the absence of smoke and unpleasant smell during the combustion of these liquids—Patent completed.

S520 J. M'Graatz, Belfast. Shirts. Dated November 19,

3520 J. M'GRATH, Belfast. Shirts. Dated November 19,

1868. This consists in applying to shirts of the ordinary shape and construction a breast or front, having a band or plate of the same or some different material or pattern, so arranged as to imitate the appearance and dispense with the use of a neck scarf. The outer ply of the band or plate extends or rises in a loose flap or tongue over and to the higher edge of the neck band, and is fastened up in that position by means of a stud or pin, or some imitation thereof, passing through it from the neck band. The under ply of the band or plate it is attached to the neck band, which may, if desired, be fastened round the neck by a button in the ordinary way.—Patent abandoned.

band, which may, if desired, be lastened round the need by a button in the ordinary way.—Patent abandoned.

3521 J. Green, Lisburne, Ireland. Manufacture of rope. This consists in treating the materials after they have been manufactured in the ordinary way, and after having been passed through a trough of water or size, as is commonly practised, by drawing the same by means of the revolving reel or reels, by which the material when finished is taken up, under and over a series of revolving cylindrical bars or free pulleys placed at intervals outside the periphery of a large drum or cylinder. These bars or pulleys are grooved so as to admit and guide the material under process, and they are borne by adjustable sugs or brackets, attached to bolts, each having a screw threaded end, and working into a socket in or upon a fixed framework at the end of the drum or cylinder, or by adjustable slot pieces in or upon said fixed framework, or by other similar adjustable bearings, by which the material under process may be subjected to a greater or less extent of contact with the drum or cylinder.—Patent completed.

3522 E. H. BAXLEY, Newington Causewsy. Carts.

contact with the drum or cylinder.—Patent completed.

3522 E. H. BAYLEY, Newington Causewsy. Carts.
Dated November 20, 1868.

This consists of the combination of a furnace and anow
melting apparatus with a cart or other vehicle, which
may or may not be used as an ordinary water cart. A
wrought-iron tank is raised on wheels, say, four in number, and has shafts or a pole fitted thereto, together with
a seat for the driver, as in ordinary water carts. At the
top of the cart, and constituting the whole of its upper
surface, except the seat for the driver, is a hopper, or
other suitable receptacle, for the snow as it is delivered
from the shovels or hods of the scavengers. The hopper
is divided into two parts, an upper and a lower chamber,
by means of a sleve or perforated plats, which prevents
the entrance of stones and other foreign bodies into the
lower chamber.—Patent abandoned.

3523 J. McGLASHAN, Dundee. Universiting ropes.

Dated

3523 J. McGlashan, Dundee. Univisiing ropes. Dated

lower chamber.—Fatent abandoned.
3523 J. McGLASHAN, Dundee. Univisiting rops. Dated
November 20, 1868.
These improvements comprise a tube or hollow spindle,
in to one end of which the rope to be untwisted is introduced. This hollow spindle, being mounted in bearings in
the framing, is made to rotate therein by means of a
toothed driving wheel, gearing with a toothed wheel fixed
on the said hollow spindle. In gear with the same
driving wheel, or with a second driving wheel of a slightly
different size, there is a toothed ring loose on the hollow
spindle, which ring revolves at a rate slightly different to
that of the hollow spindle, and which, by means of skew
bevel teeth drives a bevel wheel on the axis of a pair of
small rollers, carried by the hollew spindle. The two
rollers are placed in a plane, at right angles to the axis of
the hollow spindle, and the rope passes between and is
nipped by them. The slight differential motion of the
loose ring, which is imparted to one of the rollers, as
described, causes the rollers to feed the rope gradually
through, whilst, as they are carried round by the rotation
of the hollow spindle, they untwist it as it passes. The
rollers may be plain or fluted, or otherwise roughened,
and may be pressed together by springs or screws in order
to nip the rope.—Patent completed.

2524 J. D. Horkins, Bedford-square. Window sasker.

to nip the rope.—Patent completed.

3524 J. D. HOPKINS, Bedford-square. Window sashes.
Dated November 20, 1868.
This consists in winding the suspending cords of window sashes around drum wheels or cylinders, placed beneath the sills of the frames, or in any other convenient situation, the drum wheels or cylinders being operated upon by gearing, worked by a cranked handle, or otherwise.—Patent completed.

3526 A. GUTHRIE, Craigs, N.B. *Ploughs*. Dated November 20, 1868.

This relates to improvements in that class of ploughs in

which two or more furrows are turned simultaneously, and the whole weight of the implement is supported on wheels. The body of the plough consists of a rectangular frame, to which the coulters and mould boards are fastened in such a manner that they can be readily shifted in position, to form any required depth of furrow. The guiding and land side wheels are attached to this frame by means of adjustable levers, which will admit of the coulters and mould boards being raised or lowered, and guided so as to form two or more furrows simultaneously, of uniform breadth and depth. These levers are under the control of the attendant, and can be instantly shifted to sait the varying nature of the soil, without the necessity of stopping the horses. The axle of the hind or trailing wheel is attached by a movable bracket to the frame. This bracket is so formed that the trailing wheel can readily be shifted to a greater or less angle, so as to have more power over the mould boards.—Patent completed.

3527 A LEYKAUF. Nuremburg, Bayaria. New colouring

more power over the mould boards.—Patent completed.

3527 A. LEYKAUF, Nuremburg, Bavaria. New colouring matter. Dated November 20, 1868.

The process is best practically performed as follows:—The inventor takes pure manganese, or the cheat of chlorine, and mixes it with phosphoric acid. He heats it till fluessed. After cooling, the manganese is precipitated by ammonia, or carbonate of ammonia, and is poured, with the liquid flowing from the coarser undecomposed manganese ore, into another vessel, in which the mixture is evaporated. Iron, or an oxide or other compound, may be added for certain shades.—Patent completed.

3528 B. BRITTEN, Red Hill. Fishing rods. Dated November 20, 1868.

S528 B. BRITTEN, Red Hill. Fishing rods. Dated November 20, 1868.

Instead of wood for those parts which are required to be pliant and elastic, the inventor makes use of steel, iron or other suitable metal, of such form in transverse section as will secure the requisite longitudinal strength combined with lightness and elasticity. He makes the rods of different lengths, sizes, and proportions, and with such fittings of the ordinary kind as are required. He constructs them generally of steel or iron, in the form of tubes of very thin substance, the thickness of metal varying from about No. 25 to about No. 33 of the wire gauze. The tubes are either welded or soldered and drawn into shape in the ordinary way, and they may be either taper in length or parallel. They are hardened and tempered in the usual way, or a sufficient degree of elasticity may be obtained by slightly casebardening them by the common process, or by coating their surfaces with tallow, or other fatty matter, and heating them to a sufficient temperature to burn or carbonize the tallow, and then cooling them in the air.—Patent completed.

3529 F. D. SUTHERLAND, King William-street. Cravat

air.—Patent completed.

3529 F. D. SUTHERLAND, King William-street. Crarat holder. Dated November 28, 1868.

This consists, first, in the use of a double hook-shaped piece of metal or other material, the hooks of which are bent in opposite directions into something like the shape of the letter S flattened. Second, in making the double hook piece in two parts capable of sliding upwards, one within the other, so as to enable the compound hook-shaped piece to be adjusted to suit cravats of different widths, or the inventor employs a piece of metal formed with a hook at one end only, and a hole near the other end with a slit below.—Patent abandoned.

asso W. Brookes, Chancery-lane, W.C. Lace machinery. (A communication). Dated November 20, 1868.

This consists in doubling the size of the hole or mesh by uniting two by two the bobbin threads, which, while making the ground or not only form a single thread, but, on the contrary, are separated while making the muslin or fining. For this purpose there is employed with each set of two bobbin threads two warp threads, one of which is conducted by the stump bar and the other by one of the independent bars generally employed for gymping and embroidering.—Patent abandoned.

embroidering.—Patent abandoned.

3531 H. B. Cowrll, Islington. Distributing water.
Dated November 20, 1868.

The matter to be distributed is placed in a trough in which is supported the axis of a rotary brush, or a series of brushes, by the rotation of which, by a handle or otherwise, the matter in the trough is taken up, and then, by the edge of a plate, which may be capable of adjustment in bearing upon the surface of such brush as it revolves, the matter so taken up from the trough is spirted or thrown forwards in quantities dependent on the position of the edge of the plate in bearing upon the brush.—Patent abandoned.

Patent abandoned.

3532 W.R. Lake, Southampton-buildings. Reciprocating gauss. (A communication). Dated November 20, 1868.

This consists in imparting reciprocating motion to a scroll saw from a revolving shaft by means of flexible bands attached to the upper and lower ends of the saw, the said bands passing over suitable pulleys and being connected to pins disposed eccentrically upon driving wheels secured on the said shaft, or to bands encircling wheels secured eccentrically thereon. Rods, links, or other rigid connections between the saw and its motive power are thus dispensed with.—Patent completed.

2533 G. EGUILLON, Paris. Suspending bells. Dated

3533 G. EGUILLON, Paris. Suspending bells. Dated November 20, 1868.

This consists in suspending bells by means of three oscillating levers.—Patent completed.

8534 C. DESCAT and H. GUILLAUM, Paris. Fixing Nours. Dated November 20, 1868.

colours. Dated November 20, 1868.

This consists in the employment of metallic solutions of iron, copper, manganese, or chronium, either singly, mixed together, or in conjunction with colouring matters, for printing on textile fabrics, consisting of wool and cotton, wool and thread, goat's hair and cotton, goat's hair and thread, alpaca and cotton, alpaca and thread, and all other tissues composed of a mixture of textile, vegetable, and animal matters, either by means of the cylinder printing machine, or otherwise, the process being the same as that for printing thread tissues, thread and cotton, or cotton; the fabrics are allowed to oxydize after the application of the solutions and colouring matters, the oxydion being completed by subjecting them to an alkaline or tion being completed by subjecting them to an alkaline or bichromate bath—Patent completed.

3535 A. V. NEWTON, Chancery-lane. Secting needles. (A communication). Dated November 20, 1868.
This consists in constructing the eye with a lateral opening and an elastic hook, and an inelastic head at the root of such hook, or with the same and an inelastic abutment.—Patent completed.

and baling straw. (A communication). Dated November 20, 1868.

and baling straw. (A communication). Description 20, 1868.

The inventor first cuts the hay or straw quite short, say from one-fourth to one and one-half an inch in length, with any suitable hay cutting machine. A crushing machine is placed in close proximity, and in such relation to the cutting machine that the cut hay or straw will pass directly from the cutting machine to the crushing machine and be crushed or flattened in its passage through the machine, and thus made soft and edible. The cut or crushed hay is winnowed, or subjected to a current of air, for the purpose of removing therefrom such dust, dirt, grit, and foreign matter as may be collected therein.—Patent completed.

3537 J. G. TONGUS, Southampton-buildings. Yarns or

3537 J. G. TONGUE, Southampton-buildings. Yarns of greads. (A communication). Dated November 21, 1868. 353 J. G. TONGUE, Southampton-nullaings. Tarms or threads. (A communication). Dated November 21, 1868.; A rubbing of the thread against itself is produced by any suitable mechanism, or by causing it to interlace among or around bars having a to and fro or reciprocating movement.—Patent abandoned.

3538 J. Scholes and J. Leach, Huddersfield. Preparing

3538 J. SCHOLES and J. LEACH, Hundersheld. Preparing vool. Dated November 21, 1883.

This relates to means and apparatus for treating wool or other fibre, after being partly carded by the machine known as the "scribbler," to prepare it to be fed to either the second carding engine or the condenser carding engine. The inventors employ any ordinary means for forming the fibre into roping as it is stripped from the doffer eyinder of the scribbler. The roping is then passed between two pairs of rollers, supported on suitable framing, which deliver it upon an endless travelling belt. This belt conducts the roping from the rollers to a certain distance, where the first pair of rollers remain stationary, while the other pair continues to rotate, whereby the roping is broken or a length is separated from the remainder.—Patent abandoned.

3539 C. D. ABEL, Southampton-buildings. Tobacco pouch and cigarette former. (A communication). Dated November 21, 1868.

ber 21, 1868.

The framing of the pouch is formed of such a depth at The framing of the pouch is formed of such a depth at the top as to contain the cigarette former, the frame of which is formed by the part of the pouch frame to which is formed by the part of the pouch frame to which is hinged another part. This frame carries the three rollers, two of which are of equal diameter, while the other is ratier larger. An endless ribbon, of a width corresponding to the length of the cigarettes to be made, passes over the three said rollers, openting in similar manner to the cigarette formers now in use; a small ribbon is attached to the ribbon at the point, and serves to make the same travel in one direction or the other over the rollers, by drawing either at one end or the other. Spring catches hold part of the pouch when closed up. Two studs, by being pressed inwards, release the catches.—Patent completed.

1642 J. Bronner and H. Gutzkow, Frankfort-on-the Maine, Prussia. An improved method of obtaining anthracen out of asphaltos, that is to say, pitch produced from coal tar, and of preparing two colouring matters from the anthracen.

1643 S. and J. Prestwich, Farnworth, Lancashire. Improvements in velocipedes.

1644 J. Ingham, Valley Dye Works, Bradford, and L. Butterfield, Bradford. Improvements in machinery or apparatus for dressing warps.

1644 J. Ingham, Value Jye works, Fractord, and Fatterfield, Bradford. Improvements in machinery or apparatus for dressing warps.

1645 G. J. Pedley, Harborne, Staffordshire, and H. Grabowski, Willenhall, Staffordshire. An improved motive power for driving velocipedes, sewing machines, and for other similar purposes.

1646 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in brushes for cleaning the tubes of steam boilers.

1647 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery employed in the manufacture of bolts and nuts.

1648 G. F. Guy, Bury St. Edmunds, Suffolk. Improvements in sheathing for ships and vessels.

1649 T. Clarke, Ladyfield, Wilmslow, Chester. Improvements in the construction and working of velocipedes for use on land or water, parts of which improvements are also applicable to wheeled vehicles of every description. escription. 1650 B. C

ments are also applicable to whose twelves of every description.

1650 B. Garner, Oldbury, Worcestershire. Improvements in the bearings of axles for railway carriages and trucks, and in lubricating the said axles.

1651 F. Brown, Luton, Bedfordshire. Improvements in velocipedes called bicycles.

1652 A. T. Fairgrieve, West-street, Sunderland. An improved paste or composition adapted for coating the bottoms of wood and Iron ships.

1653 J. Fraser, Arthur-street, Park Hill-road. Liverpool, and L. and R. Simon, Hutchinson-street, Wilford-road, Nottingham. An improved machine for cutting and scoring pasteboard and similar materials one or several times at one operation.

Dated May 29, 1869.

1654 J. L. Hancock, Ley Hill, Sutton Coldfield, Warwickshire. Improvements in apparatus for making hay and harvesting corn and seeds.

1655 J. L. Hancock, Ley Hill, Sutton Coldfield, Warwickshire. Improvements in apparatus for clipping and trimming horses and other animals and for shearing sheep.

sheep.
1656 A. Hemingway, Manchester. Improvements in

1656 A. Hemingway, Manchester. Improvements in slide valves.
1657 E. J. Hughes, Manchester. Improvements in the preparation of cloth and yarn for printing and dyeing.
1658 W. H. Turner. Blackburn. Improvements in means for lessening the discharge of smoke from furnaces.
1659 J. Humphrey, Inches, Aberdeen. Improvements in the construction of iron keelson, and in the application thereof to wooden ships and vessels.
1660 J. Sturgeon, Bolton-le-Moors, Lancashire. Improvements in machinery and apparatus employed in

WILLIAM RYDER

connected with, the getting of coal and other

minerals.

1661 J. M. Muterse and H. G. de Valory, Guerande, Department de la Loire Inferieure, France. A novel lique-fiable compound substance to be used for extinguishing fires, termed anti-flame powder.

1662 A. A. Sax, Paris. An improved system of railway with helicoidal propulsion.

1663 E. Davis, Great Mitchell-street, Middlesex. Improvements in valued pades.

1663 E. Davis, Great Mitchell-street, Middlesex. Improvements in velocipedes.
1664 J. Smith, Loth, Belgium. Improvements in apparatus for holding the bobbins on the tubes or spindles of spinning and cap frames, also for regulating the drag of the thread passing on to the bobbins of common spinning

frames.

1665 J. F. Nicholls, Bristol. Converting any dining table into a billiard table in a few minutes, without injuring it or interfering with the purpose for which it was originally designed.

1666 J. J. R. Humes, Adolphus-street, Deptford, Kent. Improvements in brick moulds as applicable to brick machinery.

machinery.

Dated May 31, 1869.

1667 J. Cockshoot, jun, and H. Weatherill, Manchester.
Certain improvements in the construction of carriage axies and axie boxes.

1668 P. Kirk, Workington, Cumberland. Improvements in puddling furnaces, and in other furnaces employed in the manufacture of iron and steel.

1669 H. T. Braithwaite, Cardington-street, London. Improving two-wheeled velocipedes, commonly known as bicycles.

1670 J. Hanworth and H. Horsfall, Lancashire. Certain improvements in furnaces for steam boilers and other

purposes.

1671 R. S. Bartleet, Redditch, Worcestershire. Improvements in needle cases or needle holders.

1672 R. Littler, Cannock, Staffordshire. A new or improved guard for circular saws.

1673 J. Bullough, Accrington, Lancashire, and C. Catlow, Burnley, Lancashire. Improvements in looms for weaving.

weaving.

1674 C. E. Brooman, Fleet-street, City, patent agent.

Improvements in the construction of boilers and furnaces
for generating steam and for economizing fuel. (A com-

for generating steam and for economizing rues. (A communication),
1675 G. Preston and J. Prestige, Deptford, Kent. Improvements in lamps.
1676 R. Mathers, Leeds. Improvements in supports and mattresses for beds, couches, ottomans, sofas, and similar articles of furniture.
1677 J. Dockray, Quebec Foundry, Leeds. Improvements in carding engines.
1678 W. E. Newton, Chancery-lane. A novel device for locking corks or stoppers in bottles and other necked vessels.

vessels.

1679 D. Evans, Charles-terrace, Casland-road, South
Hackney, Middlesex. Improvements in the construction
of ships, boilers, buoys, casks, and other articles, by welding together the plates or parts of which they are formed.
1680 J. King, Walk, Norwich. An improved cinder

1680 J. King, Walk, Norwich. An improved cinder sifter.

1681 S. Birch, Belfast. Improvements applicable to handkerchief, glove, and other fancy boxes.

1682 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in mechanism for propelling and guiding vehicles, and for driving machinery by muscular

power.

1683 H. Holdrege, New York, U.S.A. Improvements in the process of making gas for illuminating, heating, and other purposes, and in apparatus for the manufacture thereof.

thereor.

1684 J. H. Johnson, Lincoln's Inn-fields. Improvements in stoves for culinary purposes.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

Science and Art.—A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brooches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[ADVI.]

LONDON: FRIDAY, JUNE 11, 1869.

THE FRENCH ATLANTIC CABLE.

A FTER many months of hard labour and excessive work the A excessive work, the position now arrived at with regard to this enterprize may fairly be termed "the beginning of the end." Not only has the whole cable been manufactured, but it has also been shipped, and a portion is now on its way to its distant resting place. On previous occasions we have informed our readers of the formation and intentions of the company, of the description of cables to be used, and, in addition, have noticed shortly the progress made in the manufacture of the work. We purpose now to consider concisely the statistics of manufacture, the division of cable upon the several vessels forming the expedition, and the final arrangements for submersion.

The length it will be as well to recapitu-The entire length of cable from France to the United States is divided into two sections, a deep sea section between Brest and the island of St. Pierre, and a shallow water section between St. Pierre and Dux-bury Cove, near Boston. The entire length, including shore ends, the intermediate shore ends, and main cable, are:—Brest to St. Pierre, 2,788 knots; St. Pierre and Duxbury, 776 knots; total, 3,564 knots. The entire amount of insulated core was manufactured at the Gutta-Percha Works at Wharf-road, and was slowly commenced on September 14, 1868, and concluded on April 15, 1869, giving a weekly average of 120 knots. This must by no means be taken as the average capacity of the works; for during a portion of that time they were not at full work, and, in addition, manufactured a large quantity of insulated core—probably about 1,000 miles.

The St. Pierre and Boston section was manufactured entirely by Mr. W. T. Henley, at his works at North Woolwich, for the contractors (the Telegraph Construction and Maintenance Company), and was commenced on January 6 and finished on May 4. The entire length of this section, including the heavy shore ends, the intermediate portion, and the main cable, each of which represents a large amount of work, when we consider the serving, the sheathing, and the outer protection of hemp and asphalte, was com-pleted at the rate of 43 knots per week. In work of this nature, there are various ele-ments which introduce delay, and, consequently, the average we have given is far below what sheathing works are capable of. But during the above-mentioned time there were many miles of other cable manufactured by Mr. Henley. However, the maximum amount of the cable manufactured by him during one week amounted to 90 knots

The major and more important portion of the contract was manufactured entirely by the Telegraph Construction and Maintenance Company at Greenwich. This consisted of the section embracing the deep sea portion between Brest and St. Pierre, and represented a length of 2,788 knots. The commencement dates from October 21, 1868, and the last portion was completed on the 2nd inst., giving an average rate of construction of about 85 knots per week. The maximum rate of manufacture was 128 knots per week, The maximum and it was actually maintained at the rate of 120 knots for some time; but when we consider the difficulty of getting material to start with, and many other points, the average rate of progress is most satisfactory. But the principal point to be considered is this, irrespective of the weekly progress, that the contract was made for the completion and shipment of the cable by a certain is considered. "Scanderia," and 450 miles more being payed out, the remainder, including the shore end at Duxbury Cove, will be completed by the tion and shipment of the cable by a certain "Chiltern." The length of the entire cable (secretary), &c., &c.

date, and that the contract has been most faithfully fulfilled. Such a fact, we maintain, is far more satisfactory and congratulatory than a mine of statistics.

A cable such as the present represents an enormous amount of work, especially if we consider some of the details. The strands of copper wire represent 25,000 miles; the weight of the insulating gutta-percha amounts to over one million pounds, put on in three separate coatings; the strands of Manilla hemp (irrespective of jute) represent a length of nearly 140,000 miles, the hemp and jute combined giving a total weight of 1,800 tons; the exterior protection of Clark's compound represents a weight of 650 tors of tar and silica; and finally, the iron wire gives a total length of over 37,000 miles, and a weight of nearly 4,700 tons, giving for the entire cable a total weight of 8,250 tons. It is when we consider such details, that the vastness of the work can really be fairly comprehended, and, under such circumstances, it is only but right and honest that due praise and acknowledgments should be given to the private companies that undertake and carry out such vast enterprises. It is the more incumbent in us to do so, when we reflect that in this particular work we alone maintain our prestige, and preserve our speciality against all comers. It is no idle boast that in this particular manufacture, we stand unrivalled. Although we may have to compete with other foreign and deserving rivals in various manufactures, yet with regard to the speciality of submarine cables, we are essentially alone. Look where we will, wherever there is an important or any submarine cable laid, it is due entirely to British manufacture, and, principally, as in the present case, to British enterprise.

The vessels employed in the expedition are The vessels employed in the expedition are the "Great Eastern," the "Scanderia," the "William Cory," and the "Chiltern," the entire amount of cable being apportioned amongst them. The "William Cory," with amongst them. The "William Cory," with the shore ends for St. Pierre, and a portion of the Boston section, has already left; the "Great Eastern," with almost the entire amount of the Brest section, leaves her present anchorage on the 12th, for Portland, and it is expected she will take her departure from there on the 18th, after receiving about 4.000 tons of coal.

The heavy shore end at Brest will be laid by the "Chiltern," for a distance of about 5½ miles; the "Great Eastern" will splice on her cable at that point, and pay out 21 miles more of heavy shore end, and will then go on to the intermediate size cable, which will carry her into deep water, and where the light deep sea cable will commence. The greatest depth is above that of the existing Atlantic cables; but the present cable is almost identical as to its mechanical construction with the former, so there is but little to fear as regards the safety of paying out. The operation of paying out is anticipated to occupy about 18 days, during which time she will be accompanied by the "Scanderia" and "Chiltern," and the cable on board the "Great Eastern" caole on board the "Great Eastern" will during that time, all be payed out, bringing her close to the island of St. Pierre. The shore end from St. Pierre and the intermediate portion will be laid by the "William Cory," and the final splice of the section completed in her. Having completed herallotted portion, the "Great Eastern" will immediately return to Sheerness. The Brest section lands at the north-east portion of the island, communication being made with the town of St. Pierre by an underground line, which is continued across the island to the southern extremity where the United States section lands. heavy shore end for this section will be laid by the "William Cory," as well as the intermediate and a portion of the main cable; from her the operations will be shifted to the

is so great that its shipment in different vessels is absolutely necessary for its speedy submersion; this involves the necessity of the entire engineering and electrical staff shifting from one ship to another. The whole of the operations are under the charge of Sir. Samuel Canning, who brought the existing Atlantic cable to a successful issue. Assisted generally by the same efficient staff, we may fairly anticipate an equal amount of success for the present cable.

The electrical arrangements are entirely under the direction of Mr. Willoughby Smith, and will be based on his special method of maintaining a constant test, while signals can, at the same time, be transmitted from ship to shore or vice versa—the system that was adopted in the 1866 Atlantic cable, and in all cables submerged by the Telegraph Construction and Maintenance Com-Mr. J. C. Laws will, it is stated, assist Mr. Smith throughout the expedition, and a conjunction of such electrical experience promises well for the success of the cable.

The entire superintendence of the cable on the part of the company has been conducted with every care and skill by their engineers, Messrs. Latimer Clark, H. C. Forde, and Fleeming Jenkin, assisted by a large staff of well-known electricians and engineers. paying out and final arrangements will also be carried out in their presence, Messrs. Clark and Forde accompanying the expedition in the "Great Eastern," while Mr. Fleeming Jenkin will remain at Brest, so as to be prepared for whatever might happen; and the result we most anxiously look forward to, is the immediate and successful issue to an undertaking so vast—an undertaking French in title, but whose success will be entirely due to English capital and English enterprise.

A grand banquet was given on board the "Great Eastern" yesterday, by the Telegraph Construction and Maintenance Company, upon the occasion of the completion and embarkation of this cable, and at which were present a number of gentlemen interested in the undertaking, as well as our leading electricians and telegraphic engineers. We understand that as soon as the "Great Eastern" has completed the task of laying this cable, she will return to Sheerness, and commence preparations for receiving the Anglo-India cable, which is intended to be laid between Suez, Aden, and Bombay, and is of the same length as the French Atlantic cable. It is also being made by the Telegraph Construc-tion and Maintenance Company.

#### THE SOCIETY OF ENGINEERS.

FOR several years past the members of the Society of Engineers have made it a practice to visit public and private works of note in and around the metropolis, as well as some of our leading engineering establish-ments, during their vacation, which extends from May to October. It has been our pleasure to accompany them on most of these visits, which have thus been the means of our placing much useful information before our readers. The first trip of the series for the present year was made on Friday last, when the members and associates of the Society and their friends visited the Limehouse Basin Improvement Works and the They West India Docks Extension Works. afterwards proceeded to the London Engineering Works at Millwall, which they inspected. There were present upon the occasion, the President (Mr. Frederick William Bryant), Mr. William Henry Le Feuvre (past president), Messrs. J. Henry Adams, James Hendry, Edward J. Leonard, and William Macgeorge, (members of council). Amongst the members were Messrs. F. E. Houghton, Thomas Car-gill, J. R. Baillie, J. Westwood, John Black-

Before describing the Limehouse Basin Improvement Works, we will give a brief history of the circumstances which necessitated them. In 1802, a canal from Paddington to the London Docks was projected, but was afterwards abandoned. In the year 1811, plans and estimates for a canal from Paddington to Limehouse, to be called the Regent's Canal, was proposed; nothing came of it until the following year, when an Act for making and maintaining a navigable canal from the Grand Junction Canal to the Thames at Limehouse, to be called the Regent's Canal, passed on July 13. The excavation was commenced in the Regent's Park on October 7 of the same year, and on August 1, 1820, the canal was opened throughout. The basin and entrances at Limehouse have, from time to time, been improved, but of late years they have been so totally inadequate for the requirements of the traffic, especially for the steam colliers, that the Company, acting under the advice of their engineer, Mr. Edwin Thomas, M.I.C.E., applied to Parliament in 1865 for powers to make a new entrance from the river, and to enlarge the dock with wharves, warehouse space, &c. Plans and estimates were at once prepared, the Company carrying out the works themselves under the immediate superintendence of their engineer, Mr. Edwin Thomas, and their resident engineer, Mr. John Blackbourn, M.S.E. The foundation stone was laid by Mr. William Parker, the chairman of the Company, on October 16, 1867, particulars of the ceremony being recorded in the MECHANICS' MAGAZINE at the time. It is expected that the works will be opened for the trade in about another month: they will have cost, with the required extra land, about £200,000. The docks are situate close to Stepney Station, and a steamboat pier is shortly to be erected with public stairs at the docks.

The works consist of a new ship entrance lock, divided into two compartments by means of three pairs of gates, the outer lock being 120ft. long, the inner 230ft. long, having a width at coping level of 60ft. 7in. The outer gate sills are 28ft. below Trinity high-water mark, the inner one 26ft. The gates are of wrought iron, the lower half being watertight, with cast-iron heel posts fitting into granite hollow quoins, no timber being used at the quoins. The mitre posts are of greenheart; the granite sills are faced with oak. There are six sluices for filling and emptying the lock chambers, each 7ft. by 4ft., and are fixed in large chambers in the gate recesses; ready access is thus afforded for examination and repairs. For flushing the bottom of the lock, there are 14 discharging culverts, ten of them, at an angle of 45deg., pointing towards the outer end of the lock, the others, at an angle of 63deg., pointing in the opposite direction. Near the river end of the lock, a swing bridge crosses on the skew. This bridge has a total largeth of 120ft. bridge has a total length of 129ft., and a clear width of 25ft. The whole of the girders are hid beneath the roadway, which is laid with cast-iron chequered plates. The bridge, with ballast, weighs about 360 tons, and is beautifully balanced. The bridge, gates, capstans, sluices, and cranes are worked by hydraulic power, the machinery for which has been supplied by Sir William Armstrong and Co., who have also constructed the whole of the ironwork.

In the river, a new quay wall, 220ft. in length, has been built; the foreshore of the river opposite this wall is to be deepened to 26ft. below Trinity high-water mark. At the west end of this wall, and east of the new entrance, a timber jetty is to be constructed, which will extend 54ft. into the river. Arrangements are made for sluicing any mud which may accumulate at the back of this present barge entrance to the new ship lock, and is 370ft. long. The walls are of solid brickwork in blue lias, faced with Portland as collectively, a great desideratum. A very prevails at the earth's surface, and, at other

cement with 2ft. of concrete at the back. The invert of the lock is 3ft. thick, laid in cement—the top course on end—with a foot of cement concrete under it. The lock walls are faced with Staffordshire blue bricks, and the dock and river walls are protected with cast-iron fenders. A coffer dam, 520ft. in length, has been erected along the river front, and consists of two rows of 13-inch sheeting piles, 6ft. apart, with counter piles every 12ft.; the dam is well strutted and bolted; at Trinity high-water there is 25ft. 6in. head of water to The dam is protected from the shipping by fender piles and floating booms. The 6ft. space is filled in with puddled yellow clay. To work the machinery, a new 80-horse power engine and three boilers are being erected; a tank to hold 50,000 gallons is placed over the boiler house. In this work, which has been well designed and equally well carried out, there 200,000 yards of excavation, of which 180,000 yards will be taken off the ground. 12,000,000 of bricks, 1,060 tons of granite, 3,700 tons of Bramley Fall, and 12,000 yards of concrete. The granite was supplied by Mr. Goodyear from the De Lank Quarries, Bod-min, Cornwall. The Bramley Fall by Messrs. Freeman and Son. The timber for the coffer dam by Messrs. Burt, Bolton, and Haywood. The whole work is a creditable example of dock engineering.

From the Limehouse Basin Works the party proceeded to the West India Dock Extension Works, where they were received by Mr. E. J. Leonard, M.S.E., the engineer of the dock company, and Mr. W. Hickson, the superintendent. Mr. Hawkshaw is the engineer for these works, which are near completion. The basin affords an area of 26½ acres of water, and with its jetties and warehouses about to be erected, will form a very important addition to the company's works. Mr. George Wythes is the contractor for the work, which is being carried out by

Mr. John Baldwin.

After having visited the foregoing works, the party adjourned to the yard of the London Engineering and Iron Shipbuilding Company, the managers of which, Messrs. Westwood and Baillie, kindly conducted the Society over their establishment, pointing out in detail the works of interest in their yard. Amongst the more prominent, we noticed the application of wrought-iron blades to screw piles. An angle-iron is riveted to the blade, following the curve of the screw the entire diameter of the pile; it is then fastened to the pile itself by means of set screws, which can be removed at pleasure. This, in itself, is a most valuable invention, not only in the simplicity of its construction, but in its easy and compact application for shipment, existing cast-iron blade and boss, together forming a most unwieldly and weighty article; besides its great liability in carriage to breakage. With the wrought-iron piles, we noticed also a very neat socket joint, the invention of Mr. Westwood, jun., for connecting long lengths of piles. This we shall take an early opportunity of placing before our readers in a more detailed form. Amongst other things, we noticed the application of curved corrugated plates for the purpose of forming a platform for bridges, thus obviating the necessity of cross girders. Two angle irons are riveted to the bottom flange of the main girders, and are carried across transversely; small tie rods are carried up from them, and connected to the plates, to prevent any tendency they might have to buckling, though, we were assured, that in bridges of small width, this precaution was quite unnecessary, the corrugated plates possessing in themselves sufficient rigidity to overcome any tendency they might have in that direction. curved corrugated plates can also be applied to the floors and roofs of buildings for India,

simple and effective means employed by Messrs. Westwood and Baillie, for obtaining the outline of dock entrances, when the tide was in, seemed to give general satisfaction. This we also hope to be enabled to give to our readers at an early date. A socket joint for cast-iron columns, in the place of flanges and bolts, as now employed, was next pointed out, with the examples on which the same test had been employed, to obtain the relative value of the one over the other; the one with the bolt holes in the flanges was fractured from end to end, whereas the one with the socket joint was as perfect as on the day it was taken from the foundry. Having made a tour of the shops, and inspected the various works in progress—amongst others, the new roof for the Great Northern Railway, at King's Cross—the members took their departure, gratified by the kindness with which Messrs. Westwood and Baillie had conducted them through their works. We have also to thank Mr. Packman for having afforded us the explanation of the construction of the various objects of interest. On leaving the London Engineering Yard, the members and their friends proceeded to the Brunswick Hotel, at Blackwall, where they dined together, and thus pleasantly brought to a close an interesting and instructive dav.

#### ON THE LAWS OF WEATHER.

KNOWLEDGE of the laws and prin-A ciples which govern the movements of the atmosphere, and apparently are the most concerned in the phenomena of weather, must be requisite to enable anyone to understand the basis of weather forecasts. propose to summarize the recognized principles of weather changes. This was a task which Admiral Fitzroy set himself to work out in "The Weather Book"—an extraordinary performance, whether we regard the subject matter or its mode of treatment. Incoherency of material and insufficiency of explanation condemn the work to neglect. The truth is, he was by no means a lucid writer. Moreover, the novel application of daily meteorological observations to the prediction of weather, which he had recently originated, was uppermost in his mind while writing, and was yet in a crude undeveloped state. He had commenced forecasting without clear perception and well conceived ideas of what could or might be accomplished. His undertaking was altogether an experiment, and such he himself termed it. Hence he necessafily corrected his impressions and his knowledge as he progressed and gained experience. He had satisfied himself of the feasibility of his scheme; but without any tentability of his scheme; but without any tentability of his scheme; tive trial, he at once made his forecasts of weather public. This accounts for the numerous and varied explanations which he sent to the newspapers to refute objectors or satisfy sceptics.

The theory of the circulation of the atmosphere recognizes two grand currents of air, blowing respectively from the equatorial and the polar regions of the earth. Hadley was the propounder of this theory, which has stood the test of all subsequent research and observation. It explains why equatorial winds come from the south-west, and polar winds from the north-east, in the northern hemisphere; why the equatorial come from north-west and the polar from south-east in the southern hemisphere. The polar current, leaving a region geographically cold, and advancing into warmer latitudes, always feels cold, and is usually dry and heavy; while the equatorial current, having a reverse course, is warm, and often moist, and light with vapour. These characteristics of the two vapour. primary wind currents are experienced gene-

times, the equatorial, and one or the other may be superposed at any given region. The place of contact, whether these currents flow side by side or one above the other, is not well defined, but is the seat of veering winds and the birthplace of storms. Regarding the north-east and the south-west as the normal winds of the north temperate zone, winds from all intermediate directions are found to bear characteristics more or less common to both normals. The place of contact or intermingling is usually marked by precipitation of rain, hail, fog, or snow, resulting from the cold of the polar current condensing the vapour borne by the equatorial current. The weather features of the polar current are generally high barometer, low thermometer for the season, dryness and clear sky; those of the equatorial are a more frequent low state of the barometer, high thermometer, rain or humidity, and overcast sky. Thus, Bacon's sayings—"Every wind sky. Thus, Bacon's sayings—"Every wind has its weather," and "North wind cold, east wind dry, south wind warm and often wet, west wind generally rainy "—have been con-

firmed by subsequent philosophy.

The chief motor of the air is undoubtedly heat, but it is not easy to trace its connection with the changes of wind, in regard to direc-tion and force, although a direct estimate of the statical forces which control the dynamical force of the wind is very much needed. Such an estimate, in the present state of science, is best obtained by means of barometers at places about 100 miles or so apart. Whenever, from any cause, a gradual lightening of the atmosphere occurs over an area of some hundreds or thousands of miles of the earth's surface, shown by barometers there falling gradually, an influx of air must of course take place to restore equilibrium. Now, it is a remarkable fact, that the direction of this flow is indicated by the motion of the mercury in the barometers, and the relation between the wind and the atmospheric pressure is such that the wind comes nearly at right angles (with tendency towards the place of deficiency), to the line joining the place of highest and the place of lowest barometer, the place of least pressure being on the left of the wind's course. This comprehensive law, for the winds of the northern hemisphere (left having to be altered to right for the southern), was first proved to be generally applicable to all winds by Dr. Ballot, of

The intermingling of polar and tropical winds causes condensation of vapour and also electrical action. These processes set free sensible heat. On the other hand, evaporation renders heat latent, and, therefore, causes chilliness. Heat thus rendered alternately latent and active, is virtually a statical force, and must affect the dynamical condition of Thus the moving force of wind must the air. result from disturbed equilibrium of atmospheric pressure, from evaporation of water, condensation of vapour, electrical action; and besides the direct influence of solar heat, there may be other agents active beyond our earth, as the attraction of the sun, moon, &c., of which, however, nothing definite is known. 'The polar current when uppermost may produce a chilling effect, and cause the lower and warmer current to part with some of its moisture; and, where the tropical current is thrown into the higher and colder region of the atmosphere there rain must happen. Thunderstorms are always the result of the conflict of two dissimilar currents of air. The contact may take place vertically, horizontally, or more or less so. When it occurs under the former circumstance, the progress of the storm marks very closely the advance of the pre-dominant wind. Under the latter circumdominant wind. Under the latter circumstances, the battle cannot be charted down, and we are left to conjecture the state of

ence of opposing winds for the occurrence of thunderstorms, has been strangely overlooked, although it is recognized even in the Psalms -"He causeth the vapours to ascend from the ends of the earth, He maketh lightnings for the rain, He bringeth the wind out of his treasures." Milton, in "Paradise Lost," savs:-

Justling, or pushed with winds, rude in their shock, Time the slant lightning; and Dryden's Virgil has this passage on the winds :-

When the winged thunder takes his way From the cold north, and east, and west, engage, And at their frontiers meet with equal rage, The clouds are crushed, &c.

Mr. Glaisher, the veteran meteorologist, observed, during a balloon ascent, made in the middle of January, a strong current of air from the south-west over our country, having a depth of nearly one mile. current continued many days. "The southwesterly current thus observed," says Mr. Glaisher, "is of the highest importance, as bearing upon the very high mean temperature we experience during the winter, so much higher than is due to our position on the earth's surface; and it is highly probable that to its fluctuations the variations of our winters are due. . . . So long as these winds blow, we have no frosts or intense colds; but the moment the wind changes during the winter to an easterly, north-easterly, or northerly direction, we have both frost and snow, and more or less intense cold. The south-west winds in their course meet with no obstruction in coming to us, but they blow directly to us and to Norway over the Atlantic; and hence we enjoy a much milder climate during winter than any other lands not similarly situated with regard to such

#### GREENWICH OBSERVATORY.

AST Saturday witnessed a gathering of philosophers in a scientific establishment, where they might revel in all the luxuries of the most refined science, elaborated to the highest pitch attainable by means of modern mechanism. The occasion was the annual official visitation at the Royal Observatory, Greenwich, by the Board of Visitors, among whom are the presidents of the Royal and the Royal Astronomical Societies, with five fellows of each body, together with the holders of astronomical chairs at Oxford and Cambridge. According to custom, a large number of scientific men met, by invitation of the chairman of the Visiting Board, to inspect the instruments and appliances unofficially. An extraordinary number of spots have lately appeared upon the sun, and these afforded great interest to the visitors, who had an opportunity of viewing them with the most powerful instrument in the observatory—an equatorial refractor of 13in. aperture and 17ft. focus. As usual upon similar occasions, the Astronomer Royal presented to the visitors his report upon the labours of the observatory during the past twelve months. This report is full of interesting matter respecting the valuable apparatus there in use. Having been favoured by the Astronomer Royal with a copy, we are enabled to place the principal points of its information before our readers.

Firstly, with regard to the buildings and grounds, we find that the middle room of the south-east dome is now completely fitted up as a chronometer room, with ample accommodation of tables for chronometers, with large chronometer oven, and with exposed railed outhouse for chronometers to be placed in the open air. The scale of all these permits the chronometer boxes to be placed, if neces-

which has been used as a temporary observatory, is at present planted as a shelter for detached telescopes and telescope stands. is intended as soon as the great shed has been removed, to erect a shed in its place, for more convenient protection of these telescopes and stands. No alteration has been made in the magnetic observatory. The precautions which the observatory staff have learned to take, and which are made effective by the incessant attention of Mr. Glashier, have enabled them to control the temperature generally without the actual change of the walls of the building. Still it is found that the effect of the sun's radiation in the south-west re-entering angle will sometimes make itself sensible; and at the present time a large wooden screen is mounted there to

ward off the heat.

At the last visitation, Professor Airy pointed out to the Hydrographer and the Director of Works to the Admiralty the too close proximity of the various buildings on the magnetic ground, and the increasing necessity for an extension of the domain of the observatory. The Professor suggested that the eastern boundary of the grounds should be extended 100ft., that the southern boundary should there be set off at right angles, and that the western boundary should be continued to meet it. The warrant for the annexation of this space to the observatory grounds received the royal signature on December 8, 1868. The new depôt for the printed productions of the observatory was in progress of construction; but in anticipation of the extension of territory, Professor Airy had so arranged its frame that it could be transported to a new position with little trouble. The new ground was extremely uneven, but by a considerable amount of earthwork and by erection of substantial retaining walls in some parts, he has been able to arrange it in two horizontal planes at different elevations. The depôt is transferred to its position in the new ground, and its internal fittings are advancing. The foundations and underpinning for the great shed are completed, and as early as possible it will be shifted from its present place on the magnetic ground to that new site. The positions selected for both these buildings are close to the new southern boundary. Great advantage will be gained to the magnetic ground, and great freedom for many purposes, by this extension of the enclosure.

No important interruption is reported as having taken place in the external galvanic communications. The courses of the wires adapted to the registration of spontaneous terrestrial galvanic currents have been entirely changed. The lines to Croydon and Deptford are abandoned, and for these are substituted a line from Angerstein Wharf to Lady Well Station, and a line from North Kent Junction to Morden College Tunnel. At each of these points the communication with earth is made by a copper plate 2ft. square. The straight line connecting the extreme points of the first station intersects that connecting the two points of the second station, nearly at right angles, and at little distance from the observatory. Great length, however, is added to the wires (apparently with no inconvenience) by the necessity of following the railways to their junction, in order to lead the wires through the projections apparatus in the through the registering apparatus in the observatory. The question of railway through Greenwich is still unsettled. After abundant consideration of this question, seeing that there is no necessity for carrying London-Woolwich passengers through Greenwich, that the construction of the great sewer will render a thorough railway far more annoying to the town of Greenwich than it might have been formerly, and that every facility for easterly communication may be given to Greenwich and to Deptford at very affairs. The presence of the upper current is shown only by the motion and visible features of clouds, most notably so by the cirrus and cirro-cumulus. The necessity for the existObservatory, it would be most advantageous to all parties (including the South-Eastern Railway Company) to lay aside all thoughts of a line through Greenwich.

Turning to the astronomical instruments, we find that the transit circle is in perfect order. A few small iron chips in the telescope tube gave some trouble; but, at the first opportunity, they were extracted by the insertion of magnets, and there has been no further annoyance. The screw movements for focal adjustments, and the jointed sliding caps for the perforations in the central cube, have been found very convenient. The reversed telescopes, for reciprocal observation through the perforated cube and for carrying the wires which are observed as meridian marks by the transit circle, when proper care is taken for focal adjustment, give no trouble in the nature of systematic discordance, and are in all respects perfectly efficient. The are in all respects perfectly efficient. The proposed high-class interior thermometer has been mounted in a position in which it may be expected to indicate fairly the temperature of the air near the object glass. Several foreign astronomers have considered this important, as they think that the computation of atmospheric refraction is more consistently accurate if it is referred to the interior thermometer than if it is made to rely on the exterior thermometer. The clocks generally are in good order. Two ounces of quick-silver were added to the bulb of the transit clock pendulum, and it does not appear to require more. Lime is used to keep the air in the head of the clock dry; it is changed once each month. A new clock by Messrs. Dent is in progress. It is to be constructed with an escapement analogous to the chronometer escapement, which produces maintaining power with a smaller amount of friction than any other. Professor Airy has arranged a method of altering the rate without stopping or touching the pendulum, by a sliding weight upon the crutch rod. He is endeavouring also to prepare a construction for altering the thermal compensation through a small extent, without touching the pendulum. He has not succeeded to his satisfaction in planning a barometrical compensation. It is proposed to place the clock in the magnetic basement, where the temperature is more uniform than in any other of the rooms, and to lead galvanic wires from it to the transit clock and other clocks.

The south-east equatoreal is in excellent condition. Very lately, the revolving arms of the re-action machine of its clockwork burst (the internal pressure of the water amounts sometimes to 50lb. per square inch), and during the absence of these arms, which describe a circle of about 15in. diameter, for repair, the arms originally constructed by Messrs. Ransomes, which describe a circle of 20in. diameter, have been substituted. With full pressure of water, the motion is now free from some very minute inequalities which could be discovered with the smaller arms. The motion of this clock, in the combination of definiteness and smoothness, is probably the most perfect in existence. The question of dependence of the measureable amount of sidereal aberration upon the thickness of glass or other transparent material in the telescope (a question which involves, theoretically, one of the most delicate points in the undulatory theory of light) has lately been agitated on the Continent with much earnestness. Professor Airy has calculated the curvatures of the lenses of crown and flint glass (the flint being exterior) for correcting spherical and chromatic aberration in a telescope whose tube is filled with water, and has directed the preparation of an instrument carrying such a telescope. The Pro-fessor has not finally decided whether to rely on zenith distances of y Draconis or on rightascensions of Polaris. In any form, the experiment will probably be troublesome.

that, on November 20, 1868, 89 Herculis, a star of the 6th magnitude, N.P.D. 64deg., was observed with the transit-circle, when passing 1hr. 50min. after the sun; and, it would appear from the Assistant's report, was observed without difficulty. The number of observed occultations of stars by the moon is four; all disappearances. The number of phenomena of Jupiter's satellites is 29. The transit of mercury on November 4, 1868, was observed by six observers; Mr. Stone using the S.E. equatoreal. The atmospheric circumstances were favourable; and the singular appearances usually presented in a planetary transit were well seen. These appearances had been observed at the Royal Observatory in a preceding transit of Mer-cury (November 8, 1848), but they had escaped from memory; and we must regard it as a fortunate circumstance that, when preparations for observing the transits of Venus in 1874 and 1882 are in agitation, we have had an opportunity of seeing, though on a somewhat different scale, the characteristic difficulties of the observation. Mr. Stone has attached to the south-east equatoreal a thermo-multiplier, with the view of examining whether heat radiating from the principal stars can be made sensible in the Observatory instruments. The results hitherto obtained are encouraging, but they show clearly that it is vain to attempt this enquiry except in the most superb weather; and there has not been a night deserving that epithet for some months past. Mr. Carpenter has made, with the south-east equatoreal, three drawings of the lunar spot Linnæus, three drawings

Jupiter, and two of Winnecke's Comet.
Continued attention has been given by Mr.
Glaisher to the equalization of the temperature of the magnetic basement, and with general good success. From October to May there is no difficulty in keeping the temperature between 59deg. and 62deg. From June to September the difficulty is much greater; on a solitary occasion, the temperature rose to 72deg. The daily change is kept down to 3deg., and in the great majority of days it does not exceed 1deg. With the system in use at the Observatory of inclosing the magnets in double boxes, every box-side being gilt within and without, the corresponding changes of temperature about the magnets are very small. This system of inclosure deserves special notice; it appears absolutely to suppress all currents of air about the magnets, and almost all causes of accidental vibration and the magnets, under the ordinary terrestrial disturbances, seem to take up their positions

without any further fluctuation. The upper declination magnet; the theodolite by which the collimator of the upper declination magnet is viewed, and which is also used to observe circumpolar stars; and the lower declination magnet, which carries the concave mirror by photographic trace is made which a photographic trace is revolving photographic barrel, are all in good order. The horizontal-force-magnet perfectly efficient. The on and its apparatus are perfectly efficient. The vertical-force-magnet is in an excellent state; its knife-edge was revised in the winter by Mr. Simms; it has exhibited no dislocations of photographic curve in the records of last

The great magnetic storm of April 15 was admirably recorded on all the instruments, but on none was it registered in greater beauty than on the vertical-force. The disturbance in that element was the greatest ever registered. A magnetic storm occurred, accompanying the aurora borealis, of May 13, comparable with that of April 15, and was equally well recorded. Professor is contemplating, as possible, a cting tracing of hour-lines in the self-acting tracing of hour-lines in the photographic sheets, but he has not yet arranged the plan. No further experiments have been made for determining the thermo-Under the head of astronomical observa- metrical corrections of the horizontal-force The issues of chronometers to the Royal tions, it may be interesting to place on record and vertical-force magnetometers. The dip-

instrument and its needles have been revised by Mr. Simms. The action of this instrument is now so delicate and so certain that it is proposed to recommence the observations at different hours of the day, which were commenced, but brought to a close many years ago. It has been the object, in establishing the plant of meteorological instruments, at Greenwich, in the first place, to introduce photographic self-registration where possible this applies to barometer and wet and dry bulb thermometers), secondly to introduce mechanical self-registration (namely, for pressure, direction, and speed of wind, and for rain fall), thirdly, to provide ample means of eye-observation (for barometer, ordinary thermometers, wet and day; thermometers at different depths in the ground; thermometers in the Thames; and seven pulviometers at different elevations). All are in good order, and have worked well through the year.

In stating last year the results obtained

from the comparison of the magnetic disturbing forces due to the spontaneous galvanic currents on seventeen selected days in the years 1865, 1866, 1867, with the magnetic disturbances actually observed, Professor Airy notified his intention of extending the comparison to all the disturbed days occurring during the use of the galvanometer apparatus in those years, and also of examining the un-disturbed days. In carrying out this plan, first, the comparison has been extended to thirty-six additional disturbed days (making fifty-three in all), and, for five of these, the curves of comparison have been drawn. The character of the results derived from the comparison is sensibly the same as that obtained from the seventeen days. Secondly, the earth current indications for all the undisturbed days have been reduced, and their results laid down in curves; their dimensions, when laid down on the same scale which makes galvanic disturbances comparsmall, and follow a law totally different from that of ordinary diurnal inequalities, having greater resemblance to the curve, or, rather, line, which would best represent luno-diurnal inequalities. The important negative result is thus obtained, that the ordinary diurnal inequalities cannot be explained by the spontaneous galvanic currents. The adjustment constants are determined for the meteoro-The adjustment logical instruments and are applied to the eye observations to the present time; and the thermometer results are reduced to the stage of exhibiting dew point and degree of moisture. The record sheets of the two anemometers are perfect in themselves. photographic sheets of the barometer and dry-and-wet thermometers are furnished with time scales to the end of 1868, and the new base line for barometer is prepared to the end of 1867. The number of rotations of the vane in 1868 is + 20.4. This record interrupts the law which had appeared to prevail for a long time, and which gave a periodical recurrence of numbers in seven years.

At the present time, the number of chronometers on hand at the Greenwich Observatory is 188, namely, 111 box chronometers, 23 pocket chronometers, and 8 deck watches. the property of the Admiralty; and 46 chronometers, the property of chronometer makers, on the annual competitive trial. The authorities have tried and have delivered to the Admiralty a chronometer to be used in trial of the speed of ships, and they have tried and reported on two chronometers intended for use in heaving the log. The system of valuation and examination is founded upon the practice of rating all the chronometers, the greater part daily and others weekly, both in the open chronometer room, whose daily range of temperature rarely exceeds 2deg., and in the oven, where a temperature not exceeding 90deg. is steadily maintained.

ķ.

sending them with balances wedged in hampers under the observatory seal by ordinary railway conveyance to the Admiralty agents at the outports. Scarcely an accident has occurred in this transmission. It is desirable, however, that some apparatus should be arranged by which the chronometer balance can be securely grasped, without the necessity for inserting cork wedges. The experience of the use of bright white steel springs instead of blue springs, as preservative against rust, is favourable, but not decisive. The error number for chronometers under trial in the year 1868 is larger by an accidental quantity than that in the last two years; it is much smaller than it was five or six years ago.

We have now taken those points in the report of the Astronomer Royal which are of chief interest to our readers. The selection, however, has not been easy where all is so interesting. We cannot conclude without noticing the personal staff by which Professor Airy is surrounded and aided: -Mr. Stone is the first or confidential assistant, and is not limited in his employment to any special class; Mr. Glashier superintends the magnetical and meteorological department; Mr. Dunkin manages the altazimuth generally and the adjustments of the meridional instruments; Mr. Ellis has the sole charge of the time department, chronometers, and time signals; Mr. Criswick is responsible for the reductions of transit circle observations in zenith distance; Mr. Lynn superintends the mass of reductions effected by the supernumerary computers, in which the transit reductions are included; Mr. Carpenter takes the care of the equatoreals, but is principally occupied with the library, the manuscripts, distribution of the printed observations, and the general literary administration of the observatory, which is very heavy; Mr. Nash assists Mr. Glashier in the magnetical and meteorological department. Professor Airy records that all these gentlemen have worked honourably, zealously, and well, in the cause of the observatory and of the sciences to which it is devoted.

#### SCIENCE FOR THE PEOPLE

THERE was a time when the knowledge of scientific truths was confined to a very few, and those few practically illustrated the axiom that "knowledge is power." Power to them it undoubtedly was; power of an oppressive and tyrannical character. The bigoted votaries of science drew a veil of impenetrable mystery around her earlier germinations, keeping the mass wondering ignorantly on in mingled fear and admiration. By degrees, the barriers of exclusiveness, set up by those who had obtained an insight into the arts and sciences, began to yield to the demand for knowledge, and, in time, the glorious light of science could no longer be kept hidden, but spread itself over many lands. Civilization taught men that "knowledge was power" only when well employed, so that they began with one accord to place their various experiences before the world, and thus promoted the healthy advance of nations. Teachers of the people arose in the land, and the people having once tested of land, and the people, having once tasted of the spring of knowledge, thirsted for more; and they have been well satisfied, for the scientific education of the mass has been the earnest study of many men. None, however, have been more practically zealous in this cause than Professor Pepper, whose name stands foremost as a teacher of the highest scientific truths in a popular form. The Royal Polytechnic Institution—the scene of his labours for many years past—bears witness to his success in instructing and, at the same time, amusing the public, and all with the purest science. Now, a man, who can command such audiences as Professor Pepper does, undoubtedly possesses a facility for Warne and Co. Bedford-street, Covent-garden. New York: Scribner, Walford and Co. 1869. the purest science. Now, a man, who can

imparting knowledge in a form which is at once striking and agreeable to all. And this requires special tact and good sense as well as talent, seeing the multifarious diversity of minds to which he has to appeal. The Pro-fessor has this talent and this tact, and we are glad to see that he has applied it in a literary direction. Professor Pepper is already known as a writer upon natural philosophy, but his earlier works were written for the vouthful student. The volume now before us is an advance upon those, and conveys scientific information to such readers as may have neither the time nor the inclination to study the more recondite authors in such a form as is at once instructive and interesting. In fact, our author transports himself, with all his happy ideas and illustrations, from the lecture theatre to a volume containing nearly 700 pages of letterpress interspersed with about 600 engravings. The subjects treated of embrace light, heat, electricity, magnetism, pneumatics, acoustics, and chemistry, which are considered in all their varied branches, their practical applications being illustrated. The various natural phenomena are explained with brevity and simplicity, and illustrations are given, by means of which the general reader is at once made familar with facts and principles, which otherwise would be but "dark sayings" to him. The author introduces here and there portions of papers, by our veterans of science upon the subjects of which he treats. Thus, amongst others, we find the names of Faraday, Daniell, Wheatstone, Brewster, Tyndall, Crookes, Siemens, Noad, Spillar, &c., whose writings are judiciously quoted in their own words, and are not hashed into a jumble by the pen of a plagiarist. Those who have been startled by the shadowy apparitions at the Polytechnic will here find them all accounted for and explained. Here, too, they will find reproduced many of those interesting experiments illustrative of the peculiar properties of light, heat, and sound, with which Professor Pepper has been wont to entertain them. In short, as a first progressive book in natural philosophy, and as one eminently calculated to stimulate the reader to a deeper research into scientific truths, we know of none which commends itself so well as Professor Pepper's "Cyclopædic Science Simplified." It is, moreover, a handsomely gotup volume, and does credit to the publishers, who have made the outside of the work as attractive as the Professor has made the

OTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS. NOTES

NEW PROCESS FOR PRESERVING WOOD—ELECTRO CHEMICAL DEPOSITION OF IRON—METHOD OF ES-TIMATING THE AMOUNT OF WATER IN STARCH OR MEAL.

NEW process for preserving wood deserves A NEW process for process as a short notice, since it offers one or two advantages over the processes commonly adopted. These, as our readers will know, consist in impregnating the wood with either a metallic solution, as sulphate of copper or sulphate of iron, or with creosote of coal tar. This last gives a disagreeable odour to the wood, and the two former more or less change the colour. In either case, the process is not adapted for floorings or other woodwork that is left exposed. The new material suggested is borax. Wood to be preserved is immersed in a saturated solution of this salt, and heat is gradually applied until the solution reaches 212deg. Fah., and it is then left for ten or twelve hours, according to the nature of the wood and the size of the planks. The wood is then to be removed from the tank, and stacked for a time, and then it is again immersed in a weaker solution of borax for about half the

ormer time. It is then to be dried, and it will be ready for use. It is advisable to dry hard woods before immersion, and put them in the solution while the wood is still warm. With this process, it will be seen that no alteration of colour is produced, and another recommendation is that the wood will be rendered very much less combustible. The rapidity with which a fire now spreads from floor to floor, as illustrated last week in Pentonville shows the great desirability of adopting some means for at least delaying the progress of the flames. We have no doubt the use of borax, as here suggested, would effect this, without adding very much to the expense of the structure. If it is desired to make the wood impermeable to water, this can be done by dissolving some shellac in the solution of borax. It would give a brownish colour to the wood, but would not be otherwise objectionable, and flooring would be rendered non-absorbent,

at all events, to cold water.

Much attention is now being paid in France to
the electro-chemical deposition of iron, and all the difficulties in the way of obtaining electrotype copies of engraved plates in this metal seem to have been surmounted by M. Feuquieres. This gentleman, however, keeps his process secret, but M. Klein is more communicative. Every salt of iron has been tried in turn for the purpose, but hitherto without success. We mentioned, three or four years ago, that Böttger had obtained the best results with iron alum, as it is called, which is really a double sulphate of iron and ammonia. It is a solution of a similar kind that Klein employs. He has tried it in various forms; first, a simple solution of iron alum, then a mixed solution of the sulphates of iron and ammonia, and, lastly, he made a solution, which he finds to answer better than either of the preceding, by first precipitating sulphate of iron with carbonate of ammonia, and then dissolving the precipitate in sulphuric acid, taking care to have a perfectly neutral solution. For the positive electrode, a sheet of iron eight times the size of the copper negative is used—that its supposing the chief is to obtain a copy in iron of is supposing the object is to obtain a copy in iron of a copperplate engraving. It was found that a good deposit of iron was not to be obtained directly upon plumbagoed gutta-percha or other moulds. It was necessary to get first upon these a very thin layer of copper, upon which the iron was deposited freely without any cracks or flaws. The copper can be removed from the iron copy by scrubbing it with a brush and rotten stone. Electro-deposited iron is, of necessity, quite pure. It is of a dull grey colour, and has rather a higher density than the best soft iron. It is malleable, but after hammering for a time it becomes brittle It cements in charcoal, and after cementation will take a temper. It may be magnetized, of course, and it retains its magnetism in a most remarkable manner when common iron loses it. This suggests the use of needles made of electro-deposited iron for magnetic observation. The uses to which the art is applied are very numerous. Besides the reproduction of copper plates in iron, dies and stamps of all kinds are reproduced in the harder

metal with manifest advantages. Chemists are often required to determine the amount of water in starches and meals, and the application of heat is not always desirable. Herr Schoibler describes another mode of removing moisture, which is quite free from objection, and which gives a very ready way of estimating the amount removed. He shakes up, say, 100 grains of the starch or meal with 200 grains of absolute alcohol, or strong alcohol of known gravity, allows the mixture to stand for about an hour, then filters off the alcohol, and takes the specific gravity, which will, of course, show the amount of dilution the alcohol has undergone by the water present in the starch. The author gives a table for calculating the results, but any chemist can easily make the calculation for himself. It is hardly present to add that due attention, must be roid. necessary to add that due attention must be paid

to temperature.

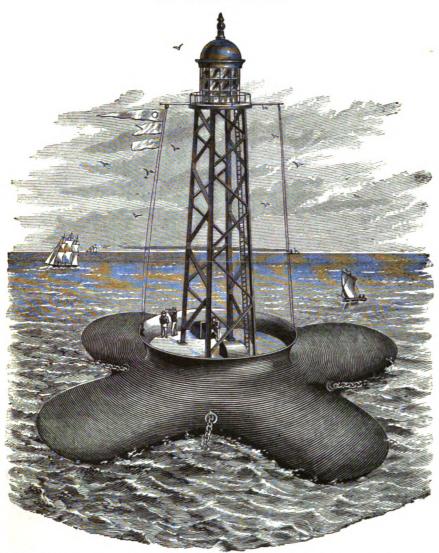

#### PARLIAMENTARY NOTES.

ON the evening of this day week, in the House of Commons, Mr. H. Palmer asked the President of the Board of Trade whether he had any objection to make a return of all railways on which there had been provided, in compliance with the Regulation of Railways Act, 1868, means of communication between the passengers and the servants of the company in charge of the trains, stating what is the nature and description of such

#### FLOATING LIGHT SHIP.

BY CAPTAIN MOODY.

respective means of communication, and what are the facilities for using the same in cases of emergency; and copy of any reports of the inspecting officers in relation thereto not already laid before the House.

Mr. Bright said it was expected that the various railways would have applied the means which were agreed upon to their rolling stock by the 1st of April, but representations had been made to the Board of Trade that that had not been done, and the time had accordingly been extended to the 1st of July. With regard to the reports asked for, he might state that a report had been pre-sented to the House by Colonel Yolland last year, and since that period nothing of importance had

and since that period nothing or importance had occurred worthy of being placed before the House.

At the same sitting, Mr. Gourley asked the First Lord of the Admiralty if he would state to the House his opinion of the ability and fitness, or otherwise, for active naval service, of the coast-guard and naval reserve seamen who composed the force recently really because the force recently really as the force recently really really as the force recently really the force recently under his command on board the Reserve Channel Squadron; if he would state in what evolutions the men and ships were exercised, and whether such as would arise out exercised, and whether such as would arise out of knowledge gained by experiments made and being made in modern warfare; and if he considered that the present ships of the Reserve Squadron would be of use for active service in the event of war, and, if so, what branch.

Mr. Childers.—In reply to my hon friend, I have to say that Admiral Key, who commanded the squadron of reserve, is about to send in a full report, with tables, of the conduct and fitness for service of the Naval Reserve and Coastguard

for service of the Naval Reserve and Coastguard men who embarked for the recent cruise. When the Admiralty have considered that report, it shall be laid upon the table with any other papers on the subject. It will also describe the evolutions and exercises of the squadron. I may, however, say in general terms that we have every reason to be satisfied with the men as a reserve, and

with their conduct. With reference to the last question, we are substituting for the old wooden dueston, we are substituting for the old wooden line-of-battle ships, which formerly were used as coastguard ships, ironclads of various types. There were three so substituted by my right hon friend opposite, and four more are now under orders to take the place of four wooden ships which went with the squadron. I hope that by the end of the year the whole of the coastguard fleet will be efficient armoured ships, and we shall thus have at our command within a few hours a squadron of nine ironclads to supplement the Channel squadron.

#### THE MOODY LIGHTSHIP.

WERE it possible to estimate the number of W vessels which are annually preserved from shipwreck through lighthouses and lightships, and the consequent number of lives spared, and value of the property saved from total loss, the aggregate sum would no doubt very much astonish even the members of the Statistical Society, clever though they be at figures. Lighthouses, however, cannot be built everywhere, and the members of the Trinity Board have admitted that the present form of lightship needs improvement. What we want is a lightship which can always carry her light, and can do for the ocean what the present gas lamps have done for our streets—enable us to see our way about, and not grope along, as in the days of the old oil lamps. The engraving which we this week present to our readers illustrates an invention which is a long stride in that direction. It is a lightship, novel in its construction, so nove

vessel from the star fish. There can be no doubt whatever that when we go to nature, and borrow our forms and designs from her works, we copy from the best models: so in this case. The four from the best models: so in this case. rays or bows which proceed from the body of the

rays or bows which proceed from the body of the ship present a floating area of immense size, and give the Moody lightship advantages it is impossible to gain from an ordinary one.

If our readers will refer to the engraving, they will perceive that there is a circular central hold, from which proceed at right angles four equal rays. The extreme ends of these rays are not fine, the theory of a ray program thin but round. The like the bows of an ordinary ship, but round. The rays are covered by sloping sides, extending to the centre of the vessel, which finishes off by an outward curved bulwark, 4ft. in height, so as to throw off the spray from the waves as they glide over the sides or run up the bows. The bottom of the lightship is flat, or nearly so, until near the edge, when it is gradually sloped to lessen the resistance when moving through the water. The slip is built in watertight compartments or bulkheads, eight being diagonal and running from the centre of the edge of each bow and the centre of each curve to join the ninth or circular bulkhead, which goes round the centre of the ship, connecting all the others. Over this central bulkhead is the upper others. Over this central bulkhead is the upper deck. The light can be carried on a tower or mast, or, as in the engraving, upon an open column — light but strong—made of angle iron. This -light but strong—made of angle 1ron. This column rises from the centre of the ship, the weight being placed over the centre of gravity. The engraving represents a lightship of the following proportions:—Length and breadth from ray to ray, 65ft.; height of light above the sea level, 60ft.; depth of hold, 12ft.; depth from water line to deck, 9ft. humarks 4ft 9ft.; bulwarks, 4ft.

There is ample room in the rays and in the centre of the ship for berths and for all other purposes. The lightship would be at all times comparatively dry, as her form would deflect the waves, so that instead of shipping heavy seas in rough weather, like an ordinary ship, the waves would be deflected and glide under and over her rays. Large scupper holes are placed round her hulwarks to carry off all waste water. It is probulwarks to carry off all waste water. It is proposed to fit her up with sails or small hydraulic engines, so that she could be readily moved from engines, so that she could be readily moved from place to place, or be under control and perfectly manageable should she from any cause break adrift, which is not very likely to happen. No difficulty would be experienced in steering her. This will be done by means of eight sluices, two at the end of each ray or bow, one on either side, but if procelled by soils those a steering approximabut if propelled by sails then a steering apparatus but it propelled by sails then a steering apparatus at the end of one of the rays. Her hawse pipes will be placed in the inner part of each curve, and in such a form that the cable can be always paid out in a line with the angle of the sides of the hull. The inventor proposes to moor her by means of three anchors in a triangular position. The advantages which this mode of mooring gives to the Moody lightship is very great indeed. The great defect in the present lightships that they roll heavily when in a cross see with is that they roll heavily when in a cross sea with a windward tide. This, of course, makes the light unsteady, and often necessitates its being lowered in a storm, when it is most needed. This, how-ever would never be the case with the Moody lightship, as her great flotation power and her four rays will prevent her rolling and pitching, and enable her to ride on the water like a gull.

The easiness with which the Moody lightship

would ride has a still greater advantage, and that is it reduces the liability of her breaking adrift. An ordinary ship in a heavy sea is very liable to snap her cable, not so much from the constant strain as from the jerking strain every time she rises after a plunge into the sea, but there would be no strain of this sort on the cables of the Moody lightship. In her case, the cables running from the central body of the ship, the four rays or bows are free to follow the motion of the waves. We understand the inventor has tested this by a small boat, 12ft. from ray to ray, which has been riding at Southend for fifteen months, and is there now. This boat has no deck covering, yet, although she outrode the winter, she never took the slightest harm nor shipped a pint of water. We have seen a report from the pier master at-Southend, who writes:—"It is with much pleasure I write to tell you how admirably your model rode this week present to our readers illustrates an invention which is a long stride in that direction. It is a lightship, novel in its construction, so nove that it is difficult clearly to describe it so as to dijustice to its inventor, Captain J. Moody, of St Maurice Villa, York. However, we will try. We understand the inventor is an old sailor, with more than fifty years of seafaring experience, and he seems to have derived the idea of the form of his during the gale was only a very small piece of bass (the same kind of rope that fishermen use). I will give her another trial the first southerly gale ve get, but am certain she will ride like a gull on

the roughest and highest seas."
We trust that we have satisfied our readers by the description we have given of this novel yet useful invention. There is no doubt that the introduction of this form of base for floating vessels will prove of great advantage. We think it is worthy of every attention, and hope the inventor will meet with the success he deserves.

#### CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

AT a meeting of this Society, held on the 2nd inst., a paper was read by Mr. Arthur C. Pain, on "The Principal Building Stones used in the Metropolis." The author confined the subject of his paper to the building stones proper, excluding paving stones and granites. It was illustrated with a map of England and Wales, showing the position and distance of the various quarries, and their means of communication with the metropolis by railway or sea. There was also a table giving the name of each, the county, name of owner, and agent in London; also the mineral and geological designation, component parts of stone, weight, chemical analysis, number of feet to the ton, average size of blocks, suitability for various purposes, the cost of working, colour, mode of working, price at quarre and the mode of working, price at quarry and at the various termini in London, as well as a few of the principal buildings in the metropolis and country constructed of each stone, with remarks on the beds, &c. The author then described chronologically as they came into use, the Kentish Rag, Gatton Fire Stone, Caen, Purbeck, Portland, Bath, Painswick, Bramley Fall, Mansfeld, Chil-Bath, Painswick, Bramley Fall, Mansfield, Chilmark, Ancaster, and Doulting. Specimens of each bed were exhibited from the quarries of Messrs. W. H. Bensted and Sons, of Maidstone; Mr. W. Carruthers, of Gatton; Mr. E. Foucard, of London and Caen; Mr. W. H. P. Weston and the Portland Stone Company, both of Portland; Messrs. Randell and Saunders, of Corsham; and Messrs. Pictor and Sons, of Box; Messrs. Husler and Co., of Headingley; Mr. Robert Lindley and Messrs. S. Fisher and Sons, both of Mansfield; the Wardour, Chilmark, and Tisbury Stone Company (Limited), of Tisbury and London; the Ancaster Stone Quarries Company, of Ancaster; and Mr. C. Trask, of Doulting; all of which have been used extensively in London. He also brought before the notice of the Society, and extinctions. hibited specimens of, the Hollington, Little Casterton, Clipsham, Forest of Dean, and Minera.

The decay of stone, its cause and prevention, having particular reference to London, was next considered. The decay, the author believed, was caused by bad selection. As a proof of this, he drew the attention of the meeting to the fact that nearly all the principal buildings in the immediate neighbourhood of each quarry were in an excellent state of preservation, while buildings in London of the same stone which had been comparatively recently built were more or less in a state of decay. He attributed this, firstly, to the fact that the masons who worked the stone for the local buildings understood the material, and knew which quarries and beds were good and rejected the bad, while the masons who worked the stone for the London buildings knew very often nothing about it, and put in good and bad without proper selection; secondly, the architect and en-gineer, in his multifarious duties, could not afford the time to study each different class of stone at the quarries, so that the specifications were very often loosely worded, of which advantage was constantly taken. He did not wish to throw blame on them, as there was no place where detail or reliable information could be obtained. The author then gave as a proof of the difficulty of obtaining information that he had devoted all his spare time for over six months in getting the results which he had laid before the society that evening, notwithstanding that the respective quarry owners and the officers of the Geological Museum and Mining Record Office had afforded

him every facility.

He then pointed out to the meeting how much this country was behind France in these matters, for M. Michelet, Chief Engineer of Roads and Bridges, had recently made a report by the direction of the French Government, on the building

subject were the Commissioners' Report, 1839, which treated generally and not in sufficient detail a few of the principal freestone quarries, leaving out hundreds of important quarries, notwithstand ing which, to prove how much a work of this kind is wanted, the report originally published at 6d. is now worth from 10s. to £1. The specimens of building stones at the Geological Museum was a step in the right direction, but the information concerning them was meagre in most cases, and on the quality of a stone if the specimen was a rough lump than if squared and faced up. The "Mineral Statistics," Part II., for 1858, published by the Mining Record Office, was a very valuable work, but it did not go deeply enough into the subject to be of great use for professional men. In conclusion, the author considered that until the heads of the professions of architecture and civil engineering, and the trades connected with the same, took the question up, and appointed an architect, engineer, chemist, geologist, builder, and practical stonemason, and an appointment of the same by the Government as royal commissioners, to report fully and collect specimens from all the principal quarries in the United Kingdom, to be put in the public museums in every large town, we should still see the stonework of our public and private structures decaying away from want of proper knowledge of the subject.

#### WHALE-CATCHING BY ELECTRICITY.

THE dangers and uncertainties to which those who are engaged in the whale fisheries are exposed render that occupation most perilous and hazardous. These dangers and uncertainties arise, firstly, from the distance at which the harpoon is necessarily thrown to strike the whale. Secondly from the unsteady motion of the boat at the time the harpoon is thrown, rendering it almost impos-sible to wound the whale in a vital part. Thirdly, from the whale, when struck, diving to the bottom of the sea, or swimming off at a great velocity and towing the boat with him, thereby frequently upsetting it, and endangering the lives of the crew. And lastly, from the whale, in his exertions to get free, breaking the line by which the harpoon is attached to the boat and escaping with it, thus rendering all the toil and labour of the crew of no avail. To obviate all this, Messrs. Bennett and Ward, of New Broad-street, City, have patented To obviate all this, Messrs. Bennett and ward, of New Broad-Street, Co., ...... a method of capturing whales by the agency of electricity, galvanism, or magnetic electricity. It consists in placing in the boat or in the whaling vessel a galvanic battery, with its coils and neces sary accompaniments, or any other electrical appa of any required intensity. Properly insulated wires are placed in connection with and pass from the opposite poles or terminals of the battery, and along the lines by which the harpoons are secured to the boat. The ends of these wires are continued to the points of the harpoons, so that points shall be in direct communication with the poles of the battery. When practicable, two harpoons are thrown into the whale at the same or nearly the same time, and when the battery is charged, the electric currents will pass along the wires to the points of the harpoons, and through the body of the whale, thus completing the electric circuit. Harpoons may be thrown simultaneously from other boats, by which means the same result will be attained. The whale (if the battery and its accompaniments are sufficiently powerful) will be paralyzed by the electric shocks, and will on or near the surface of the water without the on or near the surface of the water without the slightest motion, so that the boat can approach sufficiently near to spear and capture the fish without the possibility of the occurrence of the dangers to which we have referred.

When it is not possible to throw the two har poons at the same time into the body of the fish, it will, in some cases, be sufficient to have the extremity of one pole of the battery in the water as near to the whale as possible, while the harpoon attached to the other pole of the battery is injected into the body of the fish. Two harpoons may be bound together so as to form a single harpoon with two separate barbed points parallel to each other. the two component parts of which are insulated from each other, the wire from each pole of the battery passing down or through either part of this compound harpoon to the point, thus forming the electric circuit. Of course, in all cases where any instruments, such as harpoons, spears, &c., are likely to be brought into contact with the human

should enter into the body of the whale, as, if the poles of the battery are merely in communication with the skin of the whale, the same effect will be produced. In this way, electricity may be employed in the capture of seals and many other fish and sea or river animals.

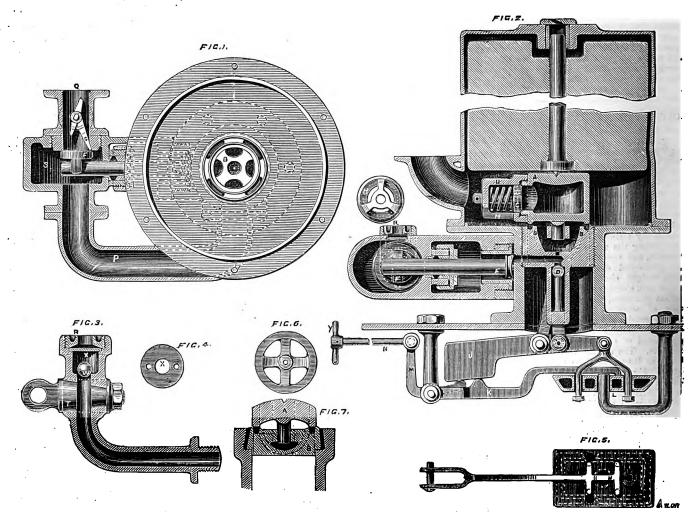

For salmon and river fishing generally, the inventors of the system propose that the insulated wires in communication with the battery shall pass through fishing rods (themselves properly insulated), the wires being continued in the form of a metallic thread properly insulated. When the salmon or other fish is hooked, another line may be thrown as near the first as possible, and the classific assessed to pass from the hook in electric current caused to pass from the hook in the fish's mouth to the other line. Or two persons may have their rods and lines in close proximity to one another during the time they are fishing, in which case no time will be lost in throwing the second line. Again, a double hook upon the same principle as the double harpoon may be employed, so that, the instant the bait is seized by the fish it will become paralyzed and unable to disgorge the bait. Another plan proposed is to have a galvanic battery placed on the bank of the river, one of its poles being placed in the water at one side, and the other conveyed across the river to the other side. It will be found that fish passing or remaining between the two terminals of the battery will be paralyzed and float at or near the top of the water, when they can be easily caught by a net or otherwise. Another proposal of the patentees is that wires from the battery shall pass partially around an ordinary net, so that fish passing into the net will be paralyzed and more easily captured. Such is the theory of fishing by electricity. The practice, however—as far as regards river fishing—will not, wethink, be followed by any true sportsman.

# THE ROYAL NATIONAL LIFEBOAT INSTITUTION.

TESTERDAY week a meeting of the above institution was held at its house, John-street, Adelphi. The minutes of the previous meeting having been read, £6 14s. was voted to pay the expenses of the Institution Lifeboat Civil Service, stationed at Wexford, Ireland, in going off in a north-east gale and heavy sea, and saving four men from the schooner "Hardy," of that port, which had parted from her anchors and gone ashore in South Bay, Wexford, on the 8th ult. Rewards were also ordered to be given to the crews of the lifeboats of the society stationed at Cahore, Wexford, Carnsore, and New Romney, for various services during the past month. The thanks of the institution, inscribed on vollum, and £1, were ordered to be presented to James Gale, coxswain of the Buckie lifeboat, £2 to F. Kerr, chief boatman of coastguard, for their sereices at that place in connexion with the lifeboat when she put off to the assistance of some fishing boats which were in distress in stormy weather off Buckie, and saved 45 lives. A reward of £2 was also granted to two men and a woman for going off and saving a woman and her son from a boat, which was overladen with sea-weed, and which sank off Whiddy Island, county Cork, on the 29th of March. The woman died from exhaustion soon after she was brought ashore. I'wo other persons had fallen overboard and perished before the arrival of the boat. Various other rewards were also granted for saving life from different wrecks. It was stated that Mr. and Mrs. Richard Thornton West had presented £700 to the institution to defray the entire cost of the lifeboat establishment to be formed on Port Isaac on the Cornish coast, and the first year's expenditure of the station. The Ancient Order of Foresters had also given the society £650 for the Foresters' No. 2 lifeboat establishment. Logacies to the amount of £500, £300, and £100, respectively, had been bequeathed to the society by the late Mr. James Sturm, of High Holborn; the late Mr. John Bewley, of Kingsland; and the late Miss Lucretia Tuckett, of Osnaburgh-street. friend to the Nottingham branch of the institution Various estimates, to the had given it £100. amount £468, for constructing lifeboat houses, and for other works at different lifeboat stations, were accepted. The whole fleet of lifeboats of the institution, now numbering upwards of 200 loats, was ordered to be painted, as usual, with the composition paint of Messrs. Peacock and Bu han, of Southampton. Payments amounting to £1,332 were made on various lifeboat establishments. A report was read from Captain D. Robertson, R.N., materials of that country, giving very detailed information, while the only works we had on the It is not absolutely necessary that the instruments visits to lifeboat stations on the Irish coast.

#### SAFETY VALVES. PATENT

BY MR. W. C. CHURCH.

Captain Robertson stated that he had everywhere found the boats in admirable order. Sir William Hall drew attention to the lamentable loss of life on recent occasions from some fishing boats of the coast of Scotland, which excited greatly the commissration of the meeting. The institution had built several safety fishing boats in Scotland, and some boats there on that model had been built.

CHURCH'S PATENT SAFETY VALVES.

WE last week described some improvements in W the slide valve by Mr. W. C. Church, of No. 2, Whitecross-place, Wilson-street, Finsbury, and No. 5, Church-street, Derby. We now proceed to notice that gentleman's improvements in safety valves and apparatus for preventing boiler explosions, as there promised. In our engraving, figs. 1 and 2 show a sectional plan and elevation of the improved safety valve, with the arrangements for preventing boiler explosions from either excessive pressure of steam, deficiency of water supply, or excessive water supply. The following is an arrangement for preventing an excessive pressure arrangement for preventing an excessive pressure of steam. A is an annular valve, with its seating B, of corresponding form; C is a valve, fitted at right angles to the valve A, for the purpose of regulating the pressure that is allowed to accumulate in the annular space or chamber of the valve A, and thereby governing the lifting power of the escaping steam upon the valve A. The steam issuing from the boiler is caused to pass circuitously both into the atmosphere and into the chamber of the valve, and the greater the pressure allowed to accumulate in this chamber, the greater will be the lifting and the greater the pressure allowed to accumulate in this chamber, the greater will be the lifting power of the escaping steam upon the valve A. By putting greater or less tension on the spiral spring of the valve C, this lifting power can be regulated to the greatest nicety, and thereby admit of a correspondingly accurate adjustment of the valve A, so as to blow off with steam at any given pressure. It is important that the area of the valve C should be equal to the area of the annular opening of the valve seating B. H is a cage for carrying the valve C. carrying the valve O.

Figs. 6 and 7 show a modification of this valve without the annular chamber, for obtaining the effect of accumulated pressure. In this case, the

effect of accumulated pressure. In this case, the increased discharging power of the valve is due to the escape upwards as well as outwards, as in the case above described, the outlet from the inner portion of the valve being at the top, as shown in fig. 7, and by dotted lines in fig. 6.

The arrangement for detecting a deficiency of water supply is shown in figs. 1 and 2. L is a float, which is worked by the rise and fall of the level of the water supplied to the boiler. Should the level of water fall from any cause beyond a given point, the weight of the float L will be caused to act on the lever J, and open the valve D, thereby allowing the steam to exort its full force upon the allowing the steam to exert its full force upon the large end of the ram E, and open the valve F, and thereby allow an amount of steam proportioned to the area of the outlet Q to blow directly on to the fire and extinguish it, if not at once attended to. The object of the throttle valve G is to enable the attendant to prevent the steam from putting out the fire, provided that he can at once supply the deficiency of water in the boiler. But before the attendant can turn the throttle valve G, he has to pass a key through the nut R, and break a glass interposed between the nut and the throttle valve, with the object of serving as a tell-tale against the attendant when broken. The glass cannot be replaced without detection, as the nut securing the glass into its place is screwed home by means of two holes, which are afterwards filled with lead,

two holes, which are afterwards filled with lead, and marked with a private stamp.

The valves F and D and the ram return to their normal positions in the following order:—When the water is again pumped to its former level, it raises the float L along with it, and takes its weight off the lever J, which at once closes the valve D, thereby removing the pressure from the large end of the ram E and allowing the contents. of the ram E, and allowing the constant pressure of the steam in the pipe P and the chest S to act upon the small end of the ram E and close the slide F, at the same time opening the throttle valve G.

Figs. 3 and 4 show a modification of the telltale for dispensing with the throttle valve G, and

which acts in the following manner: The cock i screwed into the side of the cylinder in which the large end of the ram E works, and when the steam from any cause acts upon the ram E the opening of the cock T by the attendant will instantly relieve from pressure the large end of the ram E, and allow the pressure exerted upon the small end to allow the pressure exerted upon the small end to return to its normal position. But by opening the cock T, the tell-tale glass X will be broken by the action of the steam projecting the ball W against it. This glass cannot be replaced without detection, as described.

The arrangement for detecting excess in the supply of water to the boiler is shown in figs. 12 and 15. When the float L is raised by an excess of water beyond its proper level, it will come in contact with the lever K, which will in turn raise the large end of the lever J and open the valve D, when execute the same action will take pleas with when exactly the same action will take place with the safety valve and tell-tale, as described with reference to the arrangement for providing against a deficiency of water supply. The bell orank a deficiency of water supply. The bell crank lever M is connected with the handle Y at the furnace end of the boiler by means of the connecting rod N. The use of this bell crank lever is to enable the attendant at any time to damp or put out his fire, by allowing the steam from the boiler to blow upon it. By drawing out the rod N the valve D is opened, and by pushing it in the valve is closed, without interfering with the tell-tale.

The inventor states that the patent valve will give 90 per cent more escape of steam than the mushroom valve in present use of same diameter, and will take 75 account to the patent when the patent was the patent with the patent was the patent with the patent was the patent was the patent was the patent with the patent was the patent was

and will take 75 per cent. less weight on lever to keep it to its seating.

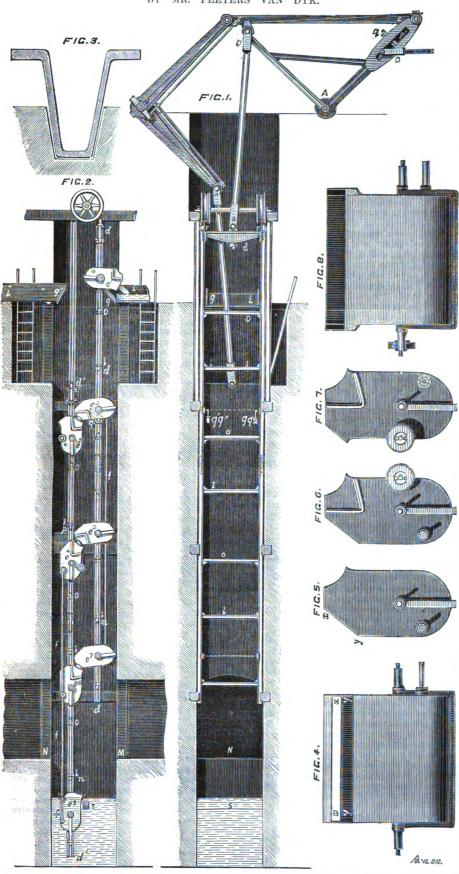

#### COMBINED MAN ENGINE AND WATER LIFT.

Eillustrate herewith a new apparatus for minwhile interest the new apparatus for min-ing purposes, which is the patented invention of Mr. Peeters Van Dyk, mining engineer of the Hague, Holland. The object here is to utilize the man engine ordinarily employed in lifting the miners as a means of lifting the water of the mine during the time the man engine is otherwise unem-

### COMBINED MAN ENGINE AND WATER LIFT.

BY MR. PEETERS VAN DYK.

ployed. For this purpose, to each shaft of the lifts of the man engine is attached a series of tipping buckets, which, alternately with each stroke of the lifts, are emptied and filled into each other, thus with every stroke of the one lift, lifting all the water in the buckets one stage, and discharging their contents into the buckets of the other lift when at its lowest point of stroke, and with each stroke discharging one bucket of water at the day level or ground level of the mine. To suspend the

action of the tipping of the buckets, whilst the men are being lifted, the man engine is constructed with a variable stroke—that is, whatever stroke is used for lifting water a portion of it will be required for the action of tipping the buckets. When the men are to be lifted the stroke is reduced by that portion, the remainder being equal to the distance apart of the landing stages for the men. The specialities of this new apparatus are, firstly, that it forms a complete system of man engine;

which it resembles, by the form of its two shafts, furnished with landing stages and their alternate and rising and falling movement. Secondly, that the water is lifted and carried by buckets, which by appropriate mechanism, tip their contents one into the other at the end of the up stroke, so that the water to be lifted is always in the shaft of the lift which is ascending.

The advantages of this apparatus over lifting pumps are as follows:—It has neither valve, piston or stuffing box. The parts subject to wear are axles moving slowly in their journals and lightly loaded. The repairs are therefore less frequent than in force pumps for great elevation; there is nothing hidden of the mechanism, so that it may be easily inspected every day. This man engine having a very great stroke (about 13ft.), can be changed into a water lifter, and allows of one shaft being used for the men and for raising water. One motive power suffices for raising water. One motive power suffices for raising water and for lifting the men—an important consideration for the mines where the engine working the man engine is only employed several hours a day. The new apparatus is preferable to pumps for irrigating lands, by reason of the working not being liable to interruption by the earthy and solid matters which river waters carry in suspension in great quantities, especially in tropical and mountainous countries.

In this apparatus, two rods a a 1 (fig. 1 of our

For a complete apparatus, three forms of buckets are required. First, a pair of buckets,  $e^7$  and  $e^8$ , fig. 2, represented separately by the two enlarged figs. 4 and 5. The buckets fill by immersion, the water entering by the opening determined by the brim xy. Second a pair of buckets,  $e^1$  and  $e^2$ , fig. 2, specially intended to empty the water at the surface of the earth, represented upon a larger scale by the figs. 7 and 8. Thirdly, pairs of intermediate buckets  $e^3 e^4 e^5 e^6$ , of fig. 2, and more clearly indicated by figs. 6 and 8. The number of these buckets, of course, depends upon the height the water has to be lifted. Each bucket in emptying makes a little more than a quarter of a revolution (about 94deg.) The number of buckets to be placed upon each lift depends upon the depth of the mine and the outfall of the water on the capacity of the buckets, and the number of strokes the lifts make in a given time. In our example, the distance of the buckets is 10ft. 6in., and the stroke of the piston is 30in. more. All the buckets of the same lift, counting from the first or highest one, are united one to the other by the rods ff, so that the movement given to one bucket is imparted to all the others.

The quarter of a revolution that the buckets should have to empty their contents one into the other is given to them by the tappets g and g. The tappets g and g, fig. 2, are placed and fixe by the side of the receptacle for the water at the surface i; they act upon the buckets e. Placing them one after the other in the position indicated at e. The two other tappets g g and g g, fig. 1 (of which one of the two only is visible, though partly hidden by the bucket e3 in the projection, fig. 2), are fixed to the wooded traverses of the shaft. Their form is simply an inclined plane, the two first tappets forming an angle of 58deg., the two others of 28deg.

From the preceding description, the working of the apparatus will be easily understood. The right lift attached to the rod a is at the end of its np-stroke whilst the left lift is at its lowest point. The bucket e<sup>8</sup> is filled by immersion, the water filling it as indicated by the arrows near y, where filling it as indicated by the arrows near y, where the side of the back part of the bucket is opened for a sufficient depth. The bucket never fills higher than the stop y, which exactly determines the quantity of water to be lifted at each stroke. All the other buckets are made of such a capacity that, after receiving the contents of the buckets e<sup>7</sup> or e<sup>8</sup>, the level of the water shall be low enough to avoid any spilling. The level of water of a full bucket ought to be about 4in. below the spout, so bucket ought to be about 41h. below the spout, so that it shall not begin to tip its contents till it is inclined 18dog. By these means, and with a well chosen form of spout, all loss is avoided in tipping one bucket of water into the other. Whilst the bucket  $e^8$  is filling by immersion in the reservoir of the shaft, the buckets  $e^6$   $e^4$  and  $e^2$  have been filled in the same time by the buckets  $e^{7}e^{5}$  and  $e^{3}$ , whilst the highest one of all,  $e^{1}$ , has poured out its contents on the surface. At each simple stroke of the piston all the buckets of the shaft which is descending are empty, whilst those upon the as-cending shaft are full. Each single stroke of the piston, therefore, carries to the surface outlet the contents of one bucket. The normal position of the buckets is vertical, as the engraving shows, for the full buckets on the left lift.

In order that the buckets shall right themselves after they are discharged, and retain that position, when they are charged up to the time they strike the tappets, each bucket is fitted at its base with a brace jointed to the axles or prolonging them so as to pass under the buckets in the form of a bent axle to give them the necessary weight to keep them constantly vertical, as shown at figs. 4, 5, 6, 7, and 8. The connecting  $\operatorname{rods} ff$  contribute also by their weight to right the buckets when the rollers quit the tappets. The righted buckets ought to rest against a pin fixed in the lifts, so that all swinging may be avoided. The traverse S serves also to right the buckets in case the counterweight has not acted. On calculating the work spent to lift the water and so tip it at the end of each stroke into the opposite buckets, and including the force absorbed by the friction of the axles and the absorbed by the inicion of the axies and the displacement of the counterpoise, also taking into account the actual weight of water put out, and comparing the force expended with the useful effect obtained, it is found to give a useful effect of 82 per cent.

In our engravings, the motion is imparted by beams attached to some motor with a rotating axle. The alternate movement of the lifts can also be more simply produced by uniting each of the lifts direct to the two cylinders of a steam engine, the cylinders being placed vertically and axially with each of the corresponding lifts. It is in this way that the man engines of the Coal Company of "L'Esperance de la Société John Cockerill de Seraing," are worked.

When the apparatus is to be used as a man engine, the buckets are emptied by tipping, to do which the connecting rods of the buckets e and e are unhooked. After which the apparatus will empty itself in m—1 strokes, when n indicates the number of buckets on a lift; the stroke is then shortened from 13ft. to 10ft. 6in. In the mechanism indicated in our design, this reduction is obtained by taking out the wedges qq of the beam A, fig. 1 and moving them slowly, which displaces the sliding block p of the connecting rod, carrying it into the second position  $p^{-1}$ ; then putting in the wedges  $q \, q$ ; the block of the connecting rod is refixed, so as to give the lists a stroke of 10ft. 6in. With a stroke of 10ft. 6in., the traverses l, &c., of the two lifts will be opposite each other or at a level with the end of each stroke. In using these traverses  $l \ l$  as landing stages for the feet, and the parallel traverses  $o \ o$  shoulder the feet, and the parallel traverses o shoulder height for the grasp of the hand of the miner when he steps out of the lift going up or down as he desires, the apparatus will be identical with the man engines, that is to say, there is no essential difference with the ordinary kind. These landing stages l m and l n, corresponding to the level of the galleries M and N, as the landing stages l d with the galleries or floars for level and l. and l with the galleries or floors for leaving A and B. It is possible to establish upon the traverse l a landing stage in wood more commodious which will hold at least two men at once. The capacity of the buckets of the dimensions indicated is 70 gallons; the apparatus not containing any water when being used as a man engine can then be used in all safety with a load up to 7 cwt. per landing stage.

AERONAUTICAL SOCIETY OF GREAT BRITAIN.

(Concluded from page 408.)

MR. R. C. JAY read a paper upon aeronautics. In describing an arrangement, which he believed entirely new, he said that his endeavour had been to design a machine, by means of which it might be possible to navigate the air by taking advantage of the various currents that might be found at different heights, and also to enable the aeronaut to ascend or descend at will. Machines sustained by hydrogen gas can never be driven against a strong wind, as, in order to obtain any great speed, there must be weight to overcome the resistar the air, and any machine lighter than an equal bulk of air would require a much more powerful engine to propel it with any degree of speed than it would be possible for it to carry, even supposing a ma-chine of that description could be made sufficiently strong. Weight, which is generally regarded as a great obstacle to the successful attainment of aerial navigation, is, in reality, an essential ele-ment of success, for without weight we could never expect to overcome the powerful element it is our aim to subdue. One circumstance, which appeared to be often overlooked, is, that a machine floating in the air is entirely separated from the earth, and that, with a given force, it will travel an equal distance through the air (not over the earth) in any direction in a given time, viz., the speed will increase until the resisting pressure of the air equals the motive force. Now, we will suppose the machine to be passing over the earth in a direction contrary to that of the wind, with a pressure of 2lb. to the square foot. If the wind suddenly increase in force the only way in which it will affect the machine will be by diminishing the speed at which it is passing over the earth but the pressure will remain the same, and there will be no more danger than there was before the will be no more danger than there was before the force of the wind increased. When a machine is regarded in this manner, as being entirely removed from the earth, it is evident that there is no more danger in a strong wind than there is in a calm, so long as the machine is under control, and sufficient for that purpose with buoyant apparatus is the power to ascend and descend at pleasure, together with a progressive speed of ten miles an hour. A machine constructed after the plan he produced would, he believed, fulfil these conditions, but he was afraid its utility would be very small and the apparatus expensive. What is required is a machine that would raise itself from the earth, and travel through the air at a speed of from two to five hundred miles per hour, and he felt convinced that it was quite possible to con-struct such a machine. The greatest difficulty seems to be the start from the earth, for when the machine is once fairly in motion, gravitation may be made to assist in obtaining the required speed In reference to propellers, he had come to the conclusion, from his own experiments, that screw fans are not of much service where there is any appreciable resistance to their progression, which must always be the case when it is necessary to ascend; and a slight restraint will cause more and more slip until the fan acts as a blower, and the machino falls back or remains nearly stationary. He was of opinion that we must regard wings as the most effective propellers even for mechanical birds, and he had no doubt that when the correct action has been discovered we shall find that they act on the air much more powerfully than the One great advantage of the wing is that it acts as a sustaining plane as well as a propeller; whereas the screw fan acts only as a propeller, and does not even sustain its own weight when used in a forward direction. He then described the plan before them. The principle on which the machine is constructed is such that when it is being driven forward the pressure of the air on the nose is nearly equal on all sides, and, with that end in view, the propellers are placed on the central line through the two sustaining gasholders. The gasholders are of silk or other suitable material, as in ordinary balloons, and are covered with netting affixed to the framework supporting the engine and car. At the bottom of the gasholders there should be some folds in the material with elastic bands to draw them tomaterial with elastic bands to draw them together, so as to keep the gas bags in shape and to allow for the expansion of the gas. The framework, composed of bamboos crossed, and strengthened by netting, may with advantage have the lower portion covered with silk or canvas, so as to form a keel which will give much greater stability to the machine, and keep its axis in the right direction. He then called the attention of

the meeting to the propellers, of novel construc-tion, which would have a considerable hold on the air. The manner in which they worked would be best understood by examining the small model he had brought with him. The propeller is very similar to a double-bladed paddle, with the blades placed at right angles; and that it has an oscillating motion at the same time that it revolves horizontally, bringing the forward blade into a perpendicular position at the commencement of stroke, and, at the same time, placing the other stroke, and, at the same time, placing the other blade in a horizontal position as it passes forward. The oscillating movement of the propeller may be obtained in a much more simple and effective manner than that shown in the model, by having a circular plate of metal round the shaft immediately below the oscillating shaft. Two slots must be cut in the plate to allow two pins, fixed in the oscillating shaft, to pass alternately over the plate as one to reverse the position of the blades the plate, so as to reverse the position of the blades of the propeller at the right moment. The propellers have also a slight shifting action at the same time that they drive the machine forward. same time that they drive the machine forward.
The motive power, as shown in the plan, is the compressed air contained in the two globular receivers, formed of alternate layers of vulcanized india-rubber and steel wire netting. These materials obtain the greatest strength combined with lightness. Each propaller (there have one one lightness. Each propeller (there being one on each side of the machine, as shown in the diagram of cross section) is furnished with a separate pair of cylinders, to enable the machine to be steered without the aid of a rudder. If one propeller be worked faster than the other, the machine will be driven out of its straight course, and may thus be carried in any direction with or across the wind. The whole machine, together with the occupants of the car, is supposed to be slightly lighter than an equal bulk of air, and it is made to ascend by moving the car backwards, so that the nose of the machine may incline upwards. The propellers will then drive forwards and upwards, and the air acting on the lower surface of the gasholders will cause the ascent to be more rapid. In descending, the car must be moved forward so as to incline the nose slightly downwards, when the effect will be the reverse of that obtained in the ascent, and the ma-chine will proceed to a lower level until the car is drawn back to the centre, when it will take a horizontal course at the will of the aeronaut. a strong wind is blowing, and a landing is con-templated, it would be well to look out for a hill or other shelter, which might break the force of the wind, and thus prevent the machine from being damaged.

Mr. Moy said he had sent a description of a plan very much like this to the MECHANICS' MAGAZINE

fourteen years ago.

Mr. Harrison asked the area of the two gasholders Mr. Jay said that would be regulated according

the weight to be carried.

Mr. Moy observed that he had made calculations, and found that there would be serious drawbacks to a machine of this kind. He found that, in order to work it, it must be 100ft. in diameter and 800ft. long. He had watched the motion of birds, and had come to the conclusion that the limit of speed is the thickness of wing.

Thanks were given to Mr. Jay for his paper.

The Chairman said it was theoretical to a great

The Chairman said it was theoretical to a great extent. There were a great many papers sent to him, but, fortunately, it was the duty of Mr. Brearey to answer puzzling questions. He would close with the remarks which he had made at the beginning of the meeting, viz., that the state of aerial navigation totally depended upon experiments that may be made, and which he hoped will be made, and, if judiciously and carefully carried out, will increase human knowledge.

It was announced that there would be another

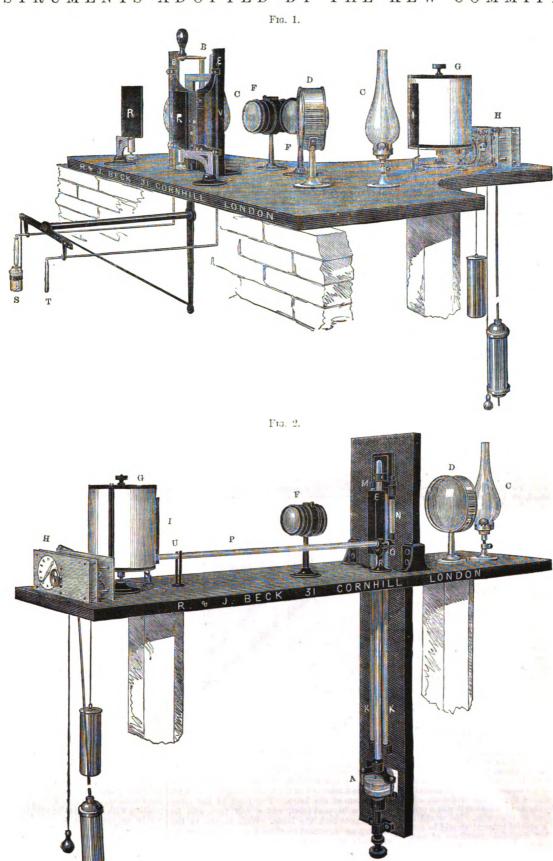

It was announced that there would be another meeting about the first week in July, provided that papers of sufficient interest would be forthcoming, and it was very desirable that members having anything in the way of models should exhbit them in the room in which they had that day met.

The thanks of the meeting were given to Captain Murray for his offer of £10, and a vote of thanks vas also given to the chairman.

The proceedings were then closed.

#### INSTRUMENTS ADOPTED B YTHE KEW COMMITTEE.

These were the thermograph and the barohill These were the thermograph and the barograph used by the Kew Committee, and which we now illustrate. The thermograph is shown at fig. 1. This instrument is designed to record the thermometric changes in the atmosphere by means of photography. The instrument, when in use, is encased in a mahogany box; all the light is excluded, save such as is admitted through an airspeck in each thermometer. The thermometer bulbs project about 1ft. from the wall upon which the edge of the slate rests. In our engraving, S is the edge of the slate rests. In our engraving, S is

the wet-bulb thermometer; T, the atmospheric thermometers to the required height; C C, the gaslights; D D, the condensers throwing the light on to the mirrors R R; and R R, the mirrors throwing the light through an air speck in the thermometers at V V. E E are the slits through which the light from the mirrors R R pass, F F are the photographic lenses throwing an image of the air speck in each of the thermometers on to the cylinder G, and G is the cylinder upon which the

this case, which fits on to the horizontal slate, is removed in the engraving to show the internal construction. A is the mercurial barometer; B, the screw for adjusting the barometer to the required height; C, the garlight; and D, the condenser, throwing the light over the top of the mercurial column, and through the slit E. E is the slit through which the light from the gaslight C passes; F, the photographic lens, throwing on to the cylinder G an image of that portion of the slit E through which the light is admitted after passing over the top of the mercurial column; G, the cylinder upon which the photographic paper is placed; and H, the clock which turns the cylinder G round once in forty-eight hours. I is the shutter which cuts off the light from the photographic paper four minutes every two hours, and so leaves a white time line when the photographic result is developed; K K are two zinc rods fastened to the vertical slate at L and sliding at M, connected with a glass rod N which rests on one end of a glass lever O, and indicates thermometric changes by means of expansion and contraction. P is a glass lever, moving on a fulcrum R, and sup-porting the end of the glass rod N at O, with a brass plate fixed on the other end U. This brass plate being attached to the glass rod P, which is in connexion with the zinc rods K K, rises and falls with every thermometric change, and by so doing exposes more or less of the lower portion of the photographic paper to the action of the light falling on it through the slit E, so that barometric changes due to temperature alone are indicated on a line on the chart, which, if such changes are considerable, becomes undulating instead of straight. The engravings are made to a scale of one-eighth full size.

#### THE LONDON ASSOCIATION OF FOREMEN ENGINEERS.

A CROWDED meeting of members and friends of this rapidly growing institution took place on Saturday last at the City Terminus Hotel. The of this rapidly growing institution took place on Saturday last at the City Terminus Hotel. The chair was filled by the president, Mr. J. Newton, of the Royal Mint, and the vice-chair by Mr. John Ives. As usual, the election of new associates, honorary and ordinary, preceded the immediate business of the sitting. Mr. Fergus Jordan, of Messrs. McGlashan's, Victoria Works, Drury-lane; Mr. Samuel Goddard, of Woolwich Arsenal; Mr. John Hoodaw, also of Woolwich Arsenal; and Mr. Welch, of Messrs. Ravenhill and Co.'s, constituted the list of new ordinary members, and Mr. N. H. Allan, of Messrs. Gwynne's, and Mr. W. M. Whieldon, of the firm of Whieldon, Lecky, and Lucas, were the honorary associates unanimously elected.

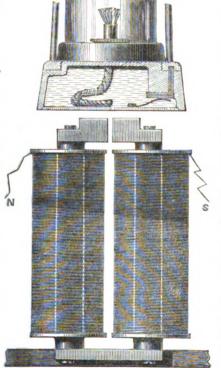

Mr. David Walker then proceeded to read a paper on the "Simplification of the Patent Laws." After defining what patent rights really mean, the author traced at considerable length and with great lucidity, the history of the patent system from the time of Queen Elizabeth to the present hour. He compated the views of Mr. Macfie, Sir Roundell Palmer, Lord Stanley and others who took part in a recent debate on the abolition of the patent laws in the House of Commons, and declared himself in favour of a sweeping amendment of the patent system, but quite opposed to abolition. Mr. Walker considered the principal evils of the present law of patents to consist in—(1) The exorbitant cost of a

system, out quite opposed to abolition. Mr. Walker considered the principal evils of the present law of patents to consist in—(1) The exorbitant cost of a patent; (2) the imperfect security it afforded to an inventor; (3) the litigation which its maintenance entailed; and (4) the cumbersome and vexations nature of the legal machinery for settling disputed questions affecting patent rights. The first demand the would make was that the original cost of a rehe would make was that the original cost of a pa-tent should be reduced to a sum not exceeding what tent should be reduced to a sum not exceeding what was absolutely necessary to cover legitimate expenses. In the next place, there should be appointed a competent body of skilled men, whose characters were above reproach, and who should be empowered to judge of the merits or defects of an invention, and decide as to whether it was a proper subject for a patent or otherwise. He would also recommend that a special tribunal should be established for deciding disputed questions of patent right. Common juries, as a rule, were quite inadequate to this task. Finally, he would ask that, as the rights of authors and inventors were absolutely analogous, so the laws relating to invention as the rights of authors and inventors were absolutely analogous, so the laws relating to invention should be assimilated as closely as possible to those of copyright. These points, the reader of the paper maintained, were of vital importance, and when they were gained the simplification of the British patent law would be an accomplished fact. The foregoing constitutes the barest possible summary of Mr. Walker's elaborate, and, it may be allowed, eloquent contribution, to the proceedings of the Foremen Engineers' Association on Saturday. It was followed by a very spirited discussion, shared in by Messrs. Humes, Thornburn, Irvine, Bragg, Muir, Shotton, Ives, Vinicombe, and others, the feeling expressed by all being favourable to the reformation rather than the destruction of the

patent system. In fact, it was manifest that the meeting was unanimously of this way of thinking. In putting the usual vote of thanks as a compliment to the author of the paper, Mr. Newton took occasion to say that he hoped another Royal Commission would ere long be nominated to examine into the whole would ere long be nominated to examine into the whole subject of patents at home and abroad. By comparing the various systems at work throughout Europe—and notably in the United States of America—with that in force in this country, data might be obtained which would be of service to the Legislature in amending our own admittedly defective patent laws. For himself, he was exceedingly glad that the question had been ventilated at a meeting such as theirs, because every member was a practical man, and most of them had had actual experience of the evils they deprecated. Certainly opinions thus formed were worthy of consideration, and they had been expressed in such a manner that ought to show us that the interests of all classes of the meshow us that the interests of all classes of the mechanical trades, and not one in particular, were recognized by the Associated Foremen Engineers. The vote was then passed by acclamation, and shortly afterwards the sitting closed.

#### LOCKING MINERS' LAMPS.

HEREWITH we illustrate the electro-magnetic lock for miners' safety lamps, which is the invention of Mr. S. P. Bidder, jun., Assoc. Inst. C.E., and which was exhibited by him at the president's conversazione. We show a portion of a miner's safety lamp in section, and the electromagnet, from which the method of operating will be seen. With this arrangement it is quite inpossible for the miner to tamper with or unlock With this arrangement it is quite imhis lamp. The lamp is self-locking. After it has been trimmed, the bottom is screwed on, and the pin, with the steel spring underneath, flies up into the upper rim; it thus prevents the bottom from

being again unscrewed until the electro-magnet is applied to the outside, and the steel armature which is immersed in the oil is brought down on the bottom of the lamp. The joint of the lamp may be a bayonet joint, and a half turn will be sufficient to lock the lamp. With regard to the locking arrangement in the oil cistern, it may be variously modified; a lever may be used with advantage, as then half the present battery power will be sufficient to work it, but the one shown in the engraving is the most simple, and is that preferred by Mr. Bidder. All the existing lamps can be altered at a small cost to work on this principle. The battery is an ordinary six-cell carbon battery, with plates 7in. by 6in. charged with sulphuric acid and water. The cost of maintenance of this would not exceed £1 5s. per annum. No ordinary magnet that could be carried about would be of sufficient

with No. 18 covered copper wire, and is arranged under a brass ring let into the lamp table. We may add that this lamp is patented by Mr. Bidder and Mr. Craig.

#### A NEW LIFE SAVING APPARATUS.

ON the evening of yesterday week some experiments were made in the river Thames, at Battersea, with a new and apparently perfect contrivance for saving life in case of shipwreck. has just been introduced into this country from America, and by it a man can live in comparative comfort in water for a considerable period. The apparatus, which is the invention of Captain Stone, of New York, consists of a cork belt, a waterproof india-rubber over-coat, a pair of propellers, and a can for provisions. The experiment was made by Mr. and Mrs. Craddock, the agents, who gave a practical explanation of the apparatus by together leaping from a barge into the river. The preleaping from a barge into the river. The pre-parations, which only occupied three minutes, were conducted in public. They first buckled cork belts round their waists, and over them they drew waterproof tunies, which covered the whole of the body, except the hands and face, around which it is fastened by elastic bands; having strapped 7lb. weights over the feet, so as to enable them to maintain their equilibrium, they were fully equipped. They took with them into the water a tin canister, in which is carried food, water, and other necessaries. This canister is most compact in its construction, in it being packed biscuits, meat, spirits, a lamp, matches, blue lights and rockets for signals, a revolver, and six quarts of water, which, being packed in a compartment at the bottom of the canister, serves to keep it in an upright position. Experiments have been tried on various parts of the Continent by Mr. and Mrs. Craddock, with marked success, and it is stated that the Prussian government have determined to adopt the apparatus. On Thursday week, Mr. and Mrs. Craddock remained in the water for a little over half an hour, and showed that they could travel with ease, although slowly, by means of travel with ease, although slowly, by means of their paddles, which are in the form of a duck's foot and fastened to the hands. The complete apparatus, it is said, will be supplied for £7, and arrangements will be made by which passengers between London and New York especially will be supplied with suits for the voyage by the payment of £1 in addition to their passage-money.

#### A NEW DEADLY WEAPON.

WE understand that a mitrailleur, or machine gun, of Belgian manufacture, will shortly arrive in this country for trial. Major G. V. Fosbery, V.C., Bengal Staff Corps, has been employed for some time on the Continent in inspecting and reporting on various specimens of this new description of arm. The Balgian witagillaur which is for some time on the Continent in inspecting and reporting on various specimens of this new description of arm. The Belgian mitraileur, which is considered the best of its class, is the invention of M. Montigny. According to the "Globe," this weapon consists of thirty-seven steel barrels, planed on the exterior to an hexagonal form, so as to fit together with ease. These barrels are then soldered in a wrought-iron tube, and fitted with a sliding breech piece, consisting of a block containing an arrangement of spiral springs for firing a central-fire cartridge in each barrel. The breech block is moved by a lever, and the turning of a handle is an arrangement of spiral springs for firing a centralfire cartridge in each barrel. The breech block is
moved by a lever, and the turning of a handle is
sufficient to fire the cartridges one by one, the
rapidity of fire being proportioned to the speed with
which the handle is made to revolve. The face of
the breech block is grooved to admit the cartridge
holder or extractor, the former being a steel plate
drilled with holes to correspond to the position of
the barrels and strikers. Several of these plates
accompany each gun, and it is asserted they can be
filled with cartridges and dropped into the proper
position with considerable ease and quickness. The
whole apparatus is mounted on a two-wheeled position with considerable ease and quickness. The whole apparatus is mounted on a two-wheeled carriage. Major Fosbery appears to have witnessed a number of experiments with this arm at the Tir National, Brussels, and at the Artillery Polygone, Brasschaet, and his report is on the whole favourable. Many missfires are recorded, due, it is said, to imperfect ammunition; but this would be unlikely to occur were Boxer cartridges employed. The experiments at Brasschaet were made at distances varying from about 430 to 1,100 yards, the target consisting of inch planks nailed to uprights, forming a screen of 97ft. in length by 9ft. in height at the two extremities, and 12ft. in height over a space of 26ft. in the centre. At 430 yards, 84 per cent. of the projectiles struck this screen; 370 cartridges were placed in the gun, which was worked by one man; of these, 40 were missfires, 278 struck, and 52 missed the target. The time was about three power to open this lamp. The lamps can be opened at the rate of 300 an hour, if required. The whole of the lamps at the Harecastle Collieries, in Staffordshire, will shortly be altered to this principle. The electro-magnet is wound round.

so difficult to obtain the correct elevation, in the absence of a properly graduated target scale, that the attempt to fire at this range was abandoned. It 370 shots per minute can be fired after some practice.

### Megal Intelligence.

VICE-CHANCELLOR'S COURT. June 8.

(Before Vice-Chancellor Sir W. M. James.)

AMORY v. BROWN.

THIS was a suit to restrain the defendant from using a patented invention relating to the ornamentation of muslins and other fabrics, of which the plaintiffs, Messrs. Amory and Eaton, trading under the title of John Heathcoat and Co., at Tiverton, are exclusive licensees. The invention consists in a new method of affixing to the surface of muslins or other fabrics drops of gum or other transparent viscous matters which, when dry, harden, and present the appearance of beads, which are either bright and transparent or coloured or opaque, as the case may be.

The defendant, who appeared in forma pauperis, besides alleging that the invention was not new, took the objection that the bill contained no averment of the novelty of the invention, or any other averment beyond a mere statement of the grant of

the letters patent.
Mr. Amphlett, Q.C., Mr. Theodore Aston, and Mr. Dundas Gardiner were for the plaintiffs; Mr. J. S. Tripp appeared for the defendant.

The Vice-Chancellor said that it was proved by

the evidence that the invention was entirely new and was one of public utility as well as elegance, and that the defendant had failed to establish any case against the patent. With respect to the objection that the bill contained no averment of novelty and utility, although it was usual, it was not absolutely necessary that the bill should contain such averments. The allegation of the grant and production of the letters patent threw upon the defendant the onus of disputing and disproving the novelty of the invention if he relied upon that defence. The decree would be for a perpetual injunction to restrain the defendant from using the invention without the licence of the plaintiffs.

The above patent was taken out in Mr. Brooman's name, and was described and illustrated in the "MECHANICS' MAGAZINE" at the time of completion.

TO CORRESPONDENTS.
THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in

advance.
All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher. Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.
To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursder avening.

ments should reach the office.
Thursday evening.
We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good

cations unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M. Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d, per line, or 5d, per line for 13 insertions, or 4d, per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertise ments.

ments.

If Mr. C. Pemberton, R.N., whose method of rifling smooth-bore guns we described and illustrated in the MECHANICS MAGAZINE for the 14th May last, will send his address, we will forward him a letter which has been

ont to our care. BENNET'S PATENT STEAM COCK.—If the manufacturer f this cock will favour us with his address we will send

#### Meetings for the Meek.

MON .- Royal Institution .- General Monthly Meeting, at

7al Institution.—General actual, according 2 p.m.
yal United Service Institution.—Rear-Admiral Sir John C. D. Hay, Bert, M.P., C.B., on "The Launch of H.M.'s Ship 'Northumberland,' "instead of the paper by Lieut. Philip Nolan, R.A., on "Finding the Range"; and Lieut.-Colonel Baillie, Bengal Staff Corps, on "The Application of Photography to Military Reconnaisance," at 8.30 p.m.

### Anbal, Military, and Gunnery Items.

THE screw steam ship "Spartan," launched a Deptford and completed at Woolwich, has had three trial trips, each of which, we understand, has proved unsatisfactory.

THE Wimbledon Prize Meeting will begin on July 5. The camp will be ready for occupation on the 3rd. Entries for the Queen's prize and the St. George's Vase closed on the 5th inst., and for all other prizes will close on the 10th.

THE large new turret ship built by Messrs. Palmer and Co., Jarrow-on-the-Tyne, for the Admiralty, made a trial trip off the Northumberland coast on Saturday, and her performance was deemed satisfactory. She left for Woolwich on Tuesday, and thence she will be despatched to Melbourne, Australia, where she will be kept for the defence of the

THE following cut from an American paper contains a nut for our long range friends to crack:—
"That's a good gun of yours, stranger, but Uncle Dave here has one that beats it." "Ah! how far will it kill a hawk with No. 6 shot?" "I don't use shot or ball cither," answered Uncle Dave himself.
"Then, what do you use, Uncle Dave?" "I shoot salt altogether. I kill my game so far with my gun that the game would spile before I could get it."

THE Hull Western Dock will be inaugurated on the 28th inst. The area of the dock is 23a. 0r. 1p., and it increases the aggregate dock area of Hull to and it increases the aggregate dock area of Hull to 84a. 0r. 16p. A banquet will be given on the occasion by the Dock Company, at Kingston-on-Hull, in one of the dock warehouses. The King's Lynn Dock Company will inaugurate its dock on July 7. The Prince and Princess of Wales will visit Lynn on the occasion, and the Prince will sustain a prominent part in the ceremony of inauguration, which will be followed by a banquet to the Royal visitors, the Lord-Lieutenant of Norfolk, and a large and distinguished party. and distinguished party.

THE Bermuda Dock, constructed by Messrs. Campbell, Johnston, and Co., will leave England on Camposii, Jonston, and Co., will leave England or about the 20th inst, convoyed by a squadron of our most powerful men-of-war. She will be towed down channel by the "Terrible," probably assisted by some smaller steam vessels. She will then be taken in charge by the "Black Prince" and "Warrior," which will see her into the latitude of Madeira, rior," which will see her into the latitude of Maderia, where, at a pre-arranged lendezvous, these ships will be relieved by the "Agincourt" and "Northumberland," which will take her within a reasonable distance from her destination, where the "Hercules" will complete the gigantic operation, by tugging her into port.

MAJOR-GEN. EDGAR GIBSON, a Peninsular and MAJOR-GEN. EDGAR GIBSON, a Peninsular and Waterloo officer, died on Tuesday week, in his 80th year. He entered the army towards the close of 1812, and was placed on half-pay in December 1839. The deceased General served in the Peninsula with the 1st Light Infantry Battalion of the King's German Legion from August, 1813, to the end of that war, in 1814, and was present at the siego of San Sebastian, an action in the Pyrenees, at the passage of the Bidasoa (where he was wounded), and in the subsequent actions in which the left wing of the army was engaged. He served also in the campaign of 1815, and was present at the battle of Waterloo. hattle of Waterloo.

ADMIRAL SIR GEORGE R. LAMBERT, G.C.B., died suddenly last Saturday evening. The deceased admiral, who was on the reserve list of flag officers, entered the navy in April, 1809, and while serving in the "Eagle" was engaged in the Walcheren expedition. He co-operated in the defence of Cadiz in 1810, and served on shore at the capture of Trieste, in 1810, and served on shore at the capture of Trieste, Fiume, and other places in the Adriatic, in 1813. He became licutenant in 1815, commander in 1822, and was posted in 1825. He served as commodore of the second class on the West India station, from January, 1847, to January, 1848. Held the same rank on the East India Station between September, 1850, and August, 1852, and subsequently as commodore of the first class, and as commander in chief.

of the first class, and as commander in chief.

A VARIED series of experiments was made last Friday at Shoeburyness. The first series upon an iron and asphalte concrete backing for iron shields, proposed by Colonel Inglis, the results obtained not being adequate to an accurate determination of its value. A new Firth's steel shell, of the same external form as the service 9-inch Palliser chilled shell, but carrying a very much larger bursting charge, and hardened only in the head, for penetration of armour, the body of the shell being of more tenacious metal, so as to permit of its passing unbroken completely through the target before bursting. The hit took place near the joint of the armour broken completely through the target before bursting. The hit took place near the joint of the armour face-plates; but the result, so far as can be stated under this circumstance, appeared to be highly satisfactory. The effect of the burst was exceedingly severe; it took place, as designed, completely in the rear. The large armour plate, 12ft. by 8ft., designed to cover entire the face of an iron shield—the rolling of which at Sir J. Brown and Co.'s works

at Sheffield we recorded some months ago—was fired at with the 7-inch rifled gun for proof. The plate was perforated with a 9lb. charge; the passage of the projectile, according to this ordinary test for 5-inch thick plates, should have been restrained by the plate. The shothole was perfectly round, and there was no starring or cracks of any kind.

### Miscellanea.

THE Liverpool town council have resolved to in vite the members of the British Association to hold their next annual meeting in Liverpool.

WE understand that the first velocipede prize at the Horse Show was awarded to Messrs. Brown and Green for their express velocipede, fitted with their patent instanter break.

MR. ALGER, of Windsor, an angler of much local MR. ALGER, of Windsor, an angles of mach recelebrity, has caught a trout weighing 1041b. at the Windsor weir. This is the finest trout that has been caught in that part of the Thames for many years.

THE conversazione of the Society of Arts, originally fixed for the 23rd inst., is unavoidably postponed to a later date, which will be announced as soon as the arrangements are completed.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending June 5, was 3,970. Total number since the opening of the Museum, free daily (May 12, 1858), 1,582,736.

It is said that the Attorney-General of the United States has given as his opinion that the cable of the French Telegraphic Company cannot be connected with the territory of the United States without the permission of Congress.

PROFESSOR BLASER, of Berlin, has been commissioned to execute a colossal bust of Alexander von Humboldt for a committee in New York. The model is now finished and has been sent to Hanover, where it will be east in bronze under the superintendence of Howaldt.

The Rev. Alexander Dyce has bequeathed to the South Kensington Museum his important dramatic library, with its unique editions of Shakespeare, and all his pictures, miniatures, antique rings, and other works of art, upon the condition that a suitable room is built to receive them.

THE Prince of Teck, the new president of the Royal Botanic Society, has issued cards of invitation to a reception and special fete at the gardens, Regent's Park, on Wednesday, June 16, at 40 clock. Should the weather be fine it is expected to be one of the best-attended meetings of the season.

THE Palestine Exploration Fund are about to open an unique exhibition at the Dudley Gallery of pottery, glass and other specimens of ancient Jewish art, found by Lieutenant Warren in the course of his excavations. There has never yet been any exhibition anywhere similar to this one.

The number of Cornish pumping-engines reported for April is 18. They have consumed 1.411 tons of coal, and lifted 10-8 million tons of water 10 fms. high. The average duty of the whole is, therefore, 51.500,0001b. lifted 1ft. high, by the consumption of 112lb. of coal.

At the general monthly meeting of the Royal Institution of Great Britain, held Monday, June 4, Mr. W. R. Grove in the chair, Mr. James Spencer Bell, the Honourable Henry M. Best, and Mr. Henry Davis Pochin, were elected members of the Royal Institution. Mr. J. B. Marsden was admitted a member of the Royal Institution.

MAJOR W. J. WILLIAMSON, in one of his reports to the Commissioner of Cooch Behar, mentions that when a Garrow father is killed by a tiger—apparently a not uncommon mode in those parts of shuffling off the mortal coil—the sous change their names, in order to throw the tiger off the scent of their identity, in case he should have a rooted names, in order to thr their identity, in case hostility to the family.

THE "Neue Freie Presse" states that the great Austrian capitalists and contractors are now directing their energies towards the development of various projects in Turkey, and adds that, in view of the great expansion of commerce which the Suez Canal and the Turkish railways will create in the empire, it is proposed, among other works of magni-tude, to make spacious harbours for the chief seaports, such as Constantinople—which is totally without accommodation of the kind—Salonica, &c.

In the Art Schools National Competition, the In the Art Schools National Competition, the following gentlemen have acted as the examiners of the works sent up in competition from the schools of art throughout the United Kingdom:—Sir Francis Grant, P.R.A.; Sir M. Digby Wyatt; Messrs. J. C. Horsley, R.A., F. Pickersgill, R.A., R. Westmacott, R.A., and E. J. Poynter A.R.A., assisted by Mr. Redgrave R.A., and Mr. Bowler. Upwards of 64,000 works have been examined in this competition. this competition.

THE green colour of leaves, one element of which must be a vegetable blue, has led an American experimentalist to the conclusion that leaves turn red at the end of the season through the action of an acid and that the green solute pould be restored by red at the end of the season through the action of an acid, and that the green colour could be restored by the action of an alkali. The conclusion has been verified by experiment,—autumnal leaves placed under a receiver with vapour of ammonia in nearly every instance lost the red colour and renewed their

For some years the western tower of Ely cathedral FOR some years the western tower of Ely cathedral has been considered unsafe. Recently some internal scaffolding to the south-west turret of the tower has been fixed, by order of the present Dean, Dr. Goodwin, who has consulted Mr. G. G. Scott as to the firmness of the walls. Oak beams and iron bracing are to be fixed to prevent the bulging of the walls, and, in fact, to prevent the fall of any part of the upper portions of the tower.

THE number of visitors to the South Kensington THE number of visitors to the South Kensington Museum during the week ending June 5, 1869, was—on Monday, Tuesday, Wednesday and Saturday (free), from 10 a.m. to 10 p.m., 15,550; Meyrick and other galleries, 2,620; on Thursday and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,478; Meyrick and other galleries, 176; total, 19,824. Average of corresponding week in former years, 11,363. Total from opening of Museum, 8,503,252.

19,824. Average of corresponding week in former years, 11,363. Total from opening of Museum, 8,503,252.

We annex a return of the quantity of coal exported from Grimsby, May, 1869:—To Russia, 3,630 tons; to France, 3,572 tons; to Egypt, 2,253 tons; to Sweden, 2,140 tons; to the Hanseatic Towns, 1,265 tons; to Norway, 1,252 tons; to Denmark, 1,193 tons; to Prussia, 1,084 tons; to Belgium, 1,006 tons; to Italy, 849 tons; to Holland, 678 tons; to British North America, 396 tons. Foreign, 19,318 tons; coastwise, 3,441 tons; total, 22,759 tons. Corresponding period, 1868, Foreign, 24,097 tons; coastwise, 3,545 tons; total, 27,642 tons—decrease, 4,883 tons.

Herring fishing, which is a comparatively new maritime industry—that is, upon anything like an extended scale, in connexion with the Tyne—has commenced very satisfactorily, Over 100 large boats were engaged in this fishing last week, the most of them Scotch, and they were very successful. There were large sales every morning at North There were large sales every morning at North Shields, and the fish would average about 6s. per 100. In another week it if anticipated nearly 200 boats will be engaged from the Tyne in this fishing.

THE arrangements for the opening of the Suez Canal in October are fully developed. The Viceroy Canal in October are fully developed. The Viceroy of Egypt proposes to entertain his guests with unprecedented magnificence. On the banks of the canal are to be erected lodges, constructed, fitted, and decorated so as to be reproductive of the characteristics of the several countries to which the guests belong. Public amusements, theatres, circuses, balls, and fetes are to be provided for the recreation of the assemblage, which promises to be as brilliant as varied in its character.

as varied in its character.

THE Merchant Taylors' Company have paid £90,000 out of their corporate funds to the Gorenors of the Charter-house, for 5½ acres of the land lately occupied by the Charter-house schools, and intend to remove their school (which is not endowed) from Suffolk-lane to that locality. They have let a portion for building purposes, but they retain 3½ acres for the school and its playground. The Metropolitan Board of Works have purchased a slip of the ground in Wilderness-row for the purpose of widening the thoroughfare, intending at some future time to continue a carriage road through to St. John-street. to St. John-street.

Dr. STARK reports that one of the most important Dr. Stark reports that one of the most important elements bearing on vital statistics is night temperature. It is the night temperature, far more than that of the day, which has the most deleterious influence on human life. He recommends that, along with the statistics of mortality, both the absolute and the mean lowest or night temperatures should be published. Experience in Scotland has shown that an excessively cold night, when the temperature falls to 10deg. or to 5deg., or below zero, the change is most fatal to the aged, to the very young, and to those weakened by disease. In some of the smaller parishes of Scotland, a cold night has been known to kill all of Scotland, a cold night has been known to kill all persons above eighty years of age; husband and wife, brother and sister, being found dead in their beds in the morning after such a night of cold.

AT a meeting of the committee of works of the lersey Docks and Harbour Board, held last Friday, Mersey Docks and Harbour Board, held last Friday, Messrs. Low and Thomas, the projectors of the proposed Liverpool and Birkenhead Railway, were present by invitation. The principal features of this scheme discussed by the board were the two piers proposed to be placed in the river, and the height of the bridge above high-water mark. One member of the committee considered that the height of 140ft. above high-water mark was insufficient, and others were of opinion that objections would be raised to the piers in the river, but this was simply their expression as individuals. Messrs Low and Thomas were referred to the consorvators of the river, and if it was referred to the consorvators of the river, and if it was found that no objection was raised by them, the committee of works thought that the Mersey Docks and Harbour Board would not raise any difficulty.

# Patents for Inbentions.

#### ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronologic al order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these sbridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

STEAM ENGINES-3546, 3550, 3568, 3600 WARFARE-3601, 3608

3540 C. Smith and J. Macfarlane, Glasgow. Washing machines. Dated November 21, 1863.

This consists in fixing ribs or feathers on the ends of the box, placed at an angle inclining upwards from each side of the box, so as to form inclined planes, meeting each other in the centre of the end. The box is moved backwards and forwards by a lever, which is attached to links centred on the ends of the box, at equal distances from the centre, and during this operation the clothes are thrown from side to side of the box overthe inclined planes hereinbefore described, and the increased agitation caused thereby effect a great saving of time and labour in the washing of clothes or other articles. In place of giving a backward and forward motion to the box containing the clothes, by means of a lever, a wheel and crank may be used.—Patent absenced.

3541 C. E. BROOMAN. Fleet-street. Manufacture of gas.

abandoned.

3541 C. E. Brooman, Fleet-street. Manufacture of gas.
Dated November 21, 1868.

The apparatus is combined with a motor which obtains its power from a portion of the gas produced, and which directly feeds the carburator or hydrocarbon reservoir with the atmospheric air necessary for generating gaseous varour.—Patent completed. vapour.—Patent completed.

with the atmospheric air necessary for generating gaseous vapour.—Patent completed.

3542 J. Sims, Liverpool-road. Ornamentingwoven fabrics. Dated November 21, 1868.

The ornaments which it is proposed to apply will take either the form of trimmings or continuous patterns or of isolated patterns or devices, and it is proposed to form them of woven fabrics of various colours and characters, as taste and circumstances may dictate, and to use in their fabrication either one such fabric or two or more of such fabrics combined. The inventor takes any desired length of these ornamental fabrics, and coats the same at the back with an adhesive substance, which will become sticky by the application of heat but will have no tendency to run and discolour the substance to which it is applied, and, when dry, will serve as an elastic cement when the trimmings or patterns are in place. The manner of coating the back of the fabric is as follows:—Upon the back of the fabric is as follows:—Upon the back of the extended silk or velvet he lays a thin sheet or film of gutta-percha, and by the application of damp heat and a moderate pressure he causes it to adhere and form a cement backing to the woven fabric. The gutta-percha thus applied will have no tendency to penetrate to the face of the woven fabric, and so injure its appearence, which would infallibly be the result if an adhesive solution were used. From compound fabrics thus produced, he proceeds to form the trimming or design.—Patent completed.

3543 J. B. HARRIS, Edinburgh. Driving bands. Dated

3543 J. B. HARRIS, Edinburgh. Driving bands. Dated November 21, 1868.

This relates to a novel mode of manufacturing driving bands, which ensures both strength and durability, at a comparatively small cost. The inventor first forms a core, composed of woven wire, embedded in a sheet of soft vulcanized india-rubber or gutta-percha or compounds of those materials. He employs one or more layers of this embedded woven wire, according to the strength of band required to form the core, and of a length and breadth determined by the size of band required to be made.—Patent abandoned.

Patent abandoned.

3544 C. J. FOSTER, Maldon. Agricultural machine:
Dated November 21, 1868.

The inventor forms around the inner periphery or rim of the motor wheel a continuous series of zig-zag slots, grooves, or projections, or they may be semicircular or curvilinear. The traversed motion desired to be produced, such as, for example, in a reaper or mower, is effected by means of a pin, projection, stud, or lever, attached to the longitudinal knife bar, entering the continuous groove, or bearing on the projections or ridges, when it follows that the revolution of the motor wheel will draw the bar to and fro, thus accomplishing the requisite reciprocating action for the cutters. The arrangements for obtaining the adhesion of the wheels is effected by means of a starred or long toothed point wheel, the teeth of which pass through the rim of the road wheel, apertures being cut in the rim of the road wheel, apertures being cut in the rim free from the slots, grooves, or projections. This

starred wheel has its bearings in a slotted guide, in connection with the axis of the motor wheel, and strengthened by the frame to which it is attached.—Patent

3545 T. W. WEBB, Bolton. Steam hammers. Dated November 23, 1868

vember 23, 1868.

The standards are now proposed to be made of Bessemer metal or cast steel, and, in order to prevent the injury caused by the sudden construction of the molten metal, the cross ribs, at each end of the moulding box, are made loose and capable of yielding when the metal is constructing. The steam cylinder is made of a plain shell of cast steel, or other metal, either cast, forged, or rolled, the ends of which fit in the crosspiece connecting the two standards, and in the cylinder cover, both of which are made of Bessemer metal or cast steel.—Patent completed.

3546 W. Inglis, Manchester. Steam engines. Dated

November 23, 1868.

The first part of the invention relates to the adaptation of separate cylindrical slide valves for steam and exhaust to the compound or high and low pressure system of steam engines. The second part of the invention relates to improved appliances for closing the steam valves of engines, or for closing any steam valves having the cut off effected or controlled by means of liberating gear.—Patent completed.

Patent completed.

3547 J. MANGNALL, Glasgow. Chairs, &c. Dated November 23, 1868

In the improved chair the oscillating part is restricted to the seat and back, with the arms, if any, which rest on a frame comprising the legs, constructed like those of any ordinary non-rocking chair. The top sides of the leg frame and the under sides of the seat frame are curved so that the latter will oscillate or rock on the former, or one may be straight and the other curved. The parts are connected by diagonal links made in any convenient way, to admit of the slight variation in their length, which the oscillating motion necessitates.—Patent abandoned.

2548 J. Rowney, M. N. and R. R. MUSS. Manchester.

oscillating motion necessitates.—Patent abandoned.

3548 J. BOWDEN, M. N. and B. R. MILLS, Manchester Carding engines. Dated November 23, 1868.

The inventors propose to introduce a roller, covered with card teeth, between the main cylinder and the doffer cylinder, to prevent the accumulation of fibres between the doffer and main cylinder, and thus to prevent the clouding or uneven thickness in the web, which is the chief cause of the web dropping or breaking between the doffer cylinder and the delivery rollers or calender rollers. They also propose to apply certain mechanical arrangements for stopping the feed rollers and doffer when the web breaks between the doffer cylinder and the draft rollers or calenders.—Patent abandoned.

calenders.—Patent abandoned.

3549 W. LA JENOTIERE, Bartholomew-road. Locks. Dated November 23, 1868.

The object of this invention is the production of a lock, which, when locked from one side, cannot possibly be opened from the opposite side, either by a similar key or any kind of pick lock. The essential characteristic of the improved lock is the use of a double bolt, one bolt sliding on or over the other, both moving in the same direction when set in motion, but each actuated by the key and slot, independently of the other from opposite sides of the lock, and each carrying a metal plate, termed by the patentee a shield, which lies close against the inner face of each lock plate, and is brought over or removed from the key hole, accordingly as the bolt carrying it is shot forward or thrown back. The key used for a lock of this improved construction is so made as to act only on the bolt upon the opposite side of the ward or guide-plate, to that by which it has been inserted, and the stem of the key does not extend beyond the end bit, so that it cannot enter the opposite key hole.—Patent completed.

3550 J. Hudson, Stockport. Steam engines. Dated No-

3550 J. HUDSON, Stockport. Steam engines. Dated No-

vember 23, 1869.

The inventor employs a square vessel having at two sides a number of ledges, and one open side, which can be closed by a plate bolted to it, and at the top an opening for the injection water, and at the bottom a nozzle connected by a pipe to the air pump. The ledges support dishes, having holes in the centre through which is passed a pipe, extending from above the vessel where it is connected to the ordinary eduction pipe.—Patent abandoned.

nected to the ordinary eduction pipe.—Patent abandoned.
3551 E. S. Hughes, Chancery-lane. Presses. (A communication). Dated November 23, 1868.

This consists in an annular wedge or annular wedges driven by power applied thereto either directly or by means of suitable gearing. This simple or compound annular wedge is the instrument by or through which the power is applied to the dies of the machine. In the application of the said annular wedge to various forms of machinery, various forms and combinations of the wedges and various subordinate devices are employed.—Patent completed.

and various supordinate devices are employed.—randa completed.

3552 J. HOULISON, Scarborough. Steeping berths. Dated November 23, 1868.

This consists in supplying sleeping accommodation or berths in railway passenger carriages, formed by fitting and arranging one, two, three, or other number of sliding or folding horizontal boards or frames of any desired width, by preference stuffed on their upper sides, and placed over the usual seats at any suitable desired heights or distances apart found most useful.—Patent completed.

3553 C. Crabtrer and J. Stell, Bingley. Paper tubes. Dated November 23, 1868.

The paper of which the tubes are to be formed is in a continuous length, and in width adapted to the length of the tubes to be produced coiled or wound upon a reel or pulley, from which it is conducted by guide pulleys to the surface of the pasting drum, which is supported by its axis, and revolves in a trough containing paste of the consistency desired. Brushes may be used, if desired, to aid the laying of the paste from a separate trough to the surface of the paper. The surplus paste is removed from the surface of the paper. The surplus paste is removed from the surface of the paper. The surplus paste is removed from the surface of the paper. The surplus paste is removed from the surface of the paper. The surplus paste is removed from the surface of the paper. The surplus paste is removed from the surface of the paper.

rollers to slide in slots or grooves formed for them, and applied to the under side or other suitable part of the carriage, one on each side of the steps, and which slots or grooves are for some distance, at their Inner ends, continued in a horizontal direction, whilst at their front or outer ends they are curved upwards to the side of the carriage, where they have recesses adapted to receive and retain the stude from the sides or connecting parts of the steps, and added by prolongations of these sides or connecting parts acting against parts of the frame in which the step slide serve to hold the steps correctly in position for use when drawn out and unfolded.—Patent completed.

nse when drawn out and unfolded.—Patent completed.

3555 W. H. IBBETT, Jewin-street, E.C. Inducing motion.
(A communication). Dated November 23, 1868.

This censists in a tube, conical or otherwise, through which the actuating body or motor is conveyed. Secondly, in a larger, longer, and similar tube, within which, and at the entrance thereof, the first-named tube is placed, the axis of both being in the same line. Thirdly, in a communication between the space outside the second tube, and the internal, between the two tubes, through which the body to be acted upon is drawn or conveyed. In some cases, the offices of the first tube and this last communication are transposed in the ancient as well as in the more modern devices, but such changes are immaterial—Patent completed.

3556 W. A. LYTTLE, Hammersmith. Electro-telegraphic apparatus. Dated November 23, 1868.

3556 W. A. LYTILE, Hammersmith. Electro-telegraphic apparatus. Dated November 23, 1868.

The inventor employs in the instrument known as the Morse printer or embosser two separate levers, with an inking roller or embosser to each, one of the levers being of soft iron and the other of magnetized steel, or iron kept constantly polarized by the proximity of a permanent magnet, and each lever having an end adjusted so as to be attracted by the electro-magnet underneath, as at present.—Patent abandoned.

sent.—Patent abandoned.

3557 J. STURROCK, Glasgow. Caps for boilles. Dated November 23, 1868.

This relates to an improved cap, to be applied to bottles or other vessels, for the purpose of sprinkling in small quantities or pouring out the liquids or fluids contained therein. The lower part of the cap is formed either of thin flexible metal, or of stiff metal, ivory, bone, wood, or other materials, and lined with cork, india-rubber, felt, or other elastic material, so as to fit tight over the neck of the bottle or other vessel. On the upper part of the cap a secondary removable cap or cover without openings is secured or otherwise fitted.—Patent abandoned.

3558 C. MONTAGU Connon-street E.C. Musical interva-

secured or otherwise fitted.—Patent abandoned.

3558 C. Montagu, Cannon-street, E.C. Musical instruments. Dated November 23, 1868.

This consists in constructing the case body or frame of the planoforte or other musical instrument of a foundation of wood or other ordinary rigid material, which, instead of being (as heretofore) veneered, is coated, covered, or faced with sheets, strips or thin pieces of india-rubber, or of a compound whereof india-rubber constitutes the main or principal ingredient. The material is moulded into form, or reduced by rolling pressure or otherwise, into thin sheets, which are cut or brought to the required shape. These are then cemented or attached to the wood or other foundation or material of the body, case, or main framing of the instrument.—Patent abandoned.

3559 A. V. Newton, Chancery-lane. Dressing millstones.

3559 A. V. NEWTON, Chancery-lane. Dressing millstones. A communication). Dated November 23, 1868.

3559 A. V. Newton, Chancery-lane. Dressing millstones, (A communication). Dated November 23, 1868.

Instead of employing the ordinary arrangement of the feed is facilitated. The sides of the furrows are parallel for the greater portion of their length, and they are formed by a combination of straight and curved lines.—Patent abandoned.

—Patent abandoned.

3560 W. E. Newton, Chancery-lane. Felted fabrics.
(A communication). Dated November 23, 1868.

This invention chiefly relates to an improved method of laying the fibre for bats, felts, waddings, and other similar goods, so that they may be crossed and interlaced in all directions for the purpose of causing them to adhere more firmly together, and thereby produce fabrics of durable quality. The fibres are formed into the bat by causing one sheet to be laid transversly back and forth on another sheet. Or on the fabric being built up is moved back and forth in the direction of its length past the place of receiving on its surface the first-mentioned sheet.—Patent completed. completed.

completed.

3561 J. R. SWANN, Edinburgh. Burning lime. Dated November 22, 1863.

The inventor provides pipes or channels surrounding the kiln or in close proximity to its sides, and he forces through such pipes or channels a current of air by means of a fan or otherwise. This air he leads into the kiln near the bottom, so that the fuel in the kiln is supplied with heated air, the cold external air being excluded.—Patent abandoned Patent abandoned.

mear the bottom, so that the fuel in the kild is supplied with heated air, the cold external air being excluded. Patent abandoned.

Patent abandoned.

3562 T. SMITH and J. N. N. BAZALGETTE, Langham Hotel, W. Deodorizing. Dated November 23, 1868.

The sewage or other fluid is introduced into the settling fank through openings in the wall of the tank at different heights, so as to obviate the disturbance caused in the process of precipitating the solid matter by the falling of the sewage stream from the upper surface of the tank wall; also communicating a slow horizontal rotary movement to the fluid at the level of its entry into the tank. A horizontal rotary motion may also be given by an open circular duct or ducts, constructed in the interior walls of the tanks delivering the sewage or other fluid at the level of the tanks delivering the sewage or other fluid at the level of the tanks and communicating a slow horizontal motion to the fluid at or near its surface. The form of the bottom of the tanks may be varied to suit the shape of the tank, whether square, round, oval, or otherwise. The bottom of the tanks may be varied to suit the shape of the tank, whether square, round, oval, or otherwise. The bottom of the tanks may be varied to suit the shape of the tank, whether square, round, oval, or otherwise. The bottom of the tanks may be varied to suit the shape of the tank is conical or pyramidal form or winking from the sides to the centre, or rising from all the sides to the centre, or at the four corners, or at the centre of the tanks is of the centre of the tanks. The deposit or residuum from the sewage on one or both sides, or at the four corners, or at the centre of the tanks into the drying beds in cases. Where the hydraulic pressure in the tanks into the drying beds in cases. Where the hydraulic pressure in the tanks into the drying beds in cases. Where the hydraulic pressure in the tanks into the drying beds in cases. Where the hydraulic pressure in the tanks into the drying beds in cases. Where the hyd

way, and so is filtered; or peat may be used as the filtering material.—Patent completed.

3563 W. H. DREAPER, Liverpool. Pianoforte hammer Dated November 23, 1864.

Dated November 23, 1803.

This consists in the use or application of india-rubber, by preference vulcanized india-rubber, in the covering of planoforte hammers.—Patent completed.

3564 J. E. PHILLIPS, Grantham. Sewing machines. Dated November 23, 1868.

3564 J. E. PHILLIPS, Grantham. Sewing machines. Dated November 23, 1868.

Two shafts or axes are employed one above and one below the cloth plate of the machine, and give motion thereto by means of toothed pinions fixed on the ends of shafts or axes driven by an internal toothed ring or wheel, as is now common with some descriptions of sewing machines, but india-rubber, gutta-percha, or compounds thereof, are employed in the construction of the gearing, in the following manner:—For the toothed pinions, the inventor first casts a boss or foundation wheel in metal with a ring or suitable projections thereon; he then places such boss or foundation wheel in a mould having suitable cavities formed therein for the teeth, and he fills the space in the mould not already occupied by the boss or foundation wheel with india-rubber, gutta-percha, or compounds thereof, and which he submits to the action of heat to "cure," and cause the compound to adhere firmly to the boss. For the internal toothed wheel or ring he first casts a plain ring of metal and then applies or forms the teeth therein in a somewhat similar manner to that described.—Patent abandoned.

3565 C. D. Abell, Chancery-lane. Cast iron. (A com-

the teeth therein in a somewhat similar manner to that described.—Patent abandoned.

3565 C. D. ABEL, Chancery-lane. Cast iron. (A communication). Dated November 23, 1868.

This process consists in mixing together cast iron and an oxide or oxides in such manner and in such proportions as to produce a solid (as distinguished from a fluid) mass, one of them being in a solid condition and the other of them a fluid state, by reason of heat applied to it previously to such mixing. The inventor uses cast iron either taken directly from the blast furnace or remelted, and for the oxydizing agent, ore crushed or pulverized may be most conveniently employed, although he does not desire to restrict himself to the use of any particular oxide. The mixing may be effected in any suitable receptacle or mould of such dimensions as will give to the resultant mass the desired shape and size. An ingot moulds, in two pieces, united and held together by bands, will answer the purpose. In the bottom of the mould he first places a small quantity of iron ore, so that the mixing may commence as soon as the melted cast iron is introduced. He then pours into the mould a stream of finely crushed iron ore, keeping the flow of each as steady as possible, and stirring them constantly with a tool (preferably madeo of wood) so as to effect an intimate admixture. Care must be taken that there shall be fully enough ore for the operation.—Patent completed.

ture. Care must be taken that there shall be fully enough ore for the operation.—Patent completed.

3566 T. CULPIN, Reading. Reaping and mowing. Dated November 24, 1868.

The beam is composed of two plates of steel fixed a given distance apart, thereby forming a trussed beam, giving greater rigidity with a given quantity of material.—Patent abandoned.

giving greater rigidity with a given quantity of material.

-Patent abandoned.

3567 J. H. Johnson, Lincoln's Inn. Raising and lowering verights. (A communication). Dated November 24, 1868. This relates, first, to certain improvements in the safety tackle, for which letters patent were granted to Pierre Joseph Jamet, dated April 3, 1865, No. 937. It is now proposed to introduce into the oscillating pulley block, described in the specification of the said patent, a binged brake which is acted upon by the fixed "crosspiece," and applies friction to the whole of the rope on the upper surface of the "return pulley" in lieu of one part only of such rope being nipped directly between the "crosspiece" and the pulley itself, whereby the rope was liable to become injured. According to the second part of this invention, the oscillating motion of the upper pulley block, as well as the special return pulley itself, are dispensed with, a ratchet wheel and detent hinged to a brake being substituted therefor. The ratchet wheel is mounted upon the axis of the sheaves, and into the tech of this ratchet wheel engages the detent which is hinged to the brake.—Patent completed.

3568 W. G. BEATHIE, Surbiton. Slide valves. Dated No-

3568 W. G. BEATTIE, Surbiton. Slide valves. Dated November 24, 1868.

abse W. G. BEATTH, SURDION. Side vaives. Dated Nomember 24, 1868.

This consists in constructing slide valves in such a
manner as to relieve them from or to reduce the pressure
of the steam thereon, and the consequent friction attending
their movement. For this purpose the inventor forms
the valve and the interior of the steam chest of a cylindrical
shape, and extends the steam ports partly round its circumference. He forms the steam port bars of loose circular
rings of metal, or other suitable material, in one or more
parts inserted in grooves in the steam chest, and compressed against the cylindrical valve by spiral or other
metallic springs, or by an adjusting screw arranged to
draw the ends of the rings together, so as to form a steamtight contact with the valve, and to compensate for the
wear of the valves and rings.—Patent completed.

3570 W. Carrer, Masham. Communicating in trains.

tension opposing each other; and the necessity of employing stays, as in iron fences, at present in use, is obvisted, stays, as in iron fences, at present in use, is obviated whilst the construction of a stronger fence is obtained-Patent completed.

Patent completed.

2573 H. E. NEWTON, Chancery-lane. Atmospheric hammers. (A communication.) Dated November 24, 1868. This relates to that class of hammers in which a cushion of confined atmosphere interposes between the lifting and striking power and the hammer itself, so that concussion on the actuating mechanism is relieved. A revolving crank and pitman, connected to a piston rod, is made use of. The piston of the rod is in an air cylinder, formed in the hammer itself. The piston rod passes through a stuffing box, and hence the confined air in the cylinder above the piston forms a cushion for lifting the hammer, and the air below the piston forms a cushion in striking the blow.—Patent completed.

Multiplying motion.

striking the blow.—Patent completed.

3574 H. E. NEWTON, Chancery-lane. Multiplying motion. (A communication.) Dated November 24, 1868.

The shaft is supported on the standards and carries the bevel wheel or disc, which is keyed thereto. The standard has a slot, to receive the pinion to connect the wheels. One of the wheels is cogged on both sides, and revolves loosely on the shaft. A lever or disc is made fast on the shaft, and carries a pinion which gears into this wheel, and also into a similar wheel, which also drives two similar wheels. All these wheels are provided with slotted lugs, to receive pinions for transmitting motion from one to the other. The two wheels last mentioned are allowed to revolve on the shaft.—Patent completed.

are allowed to revolve on the shaft.—Fatent completed.

3575 E. R. WETHERED, Shorncliffe. Signalling in trains.
Dated November 24, 1868.

The inventor arranges the apparatus in such a manner that in each carriage, or in a carriage or carriages, intermediate of the length of the train, power is stored up, either in a raised weight or spring, and this power is held available for giving the signal whenever required. The connections between the carriages are such that when the weight or spring is liberated in one carriage, it releases the weight or spring in the next carriage or carriages so furnished, and so throughout the train.—Patent completed.

3576 B. SOLOMONS, Albemarle-street, W. Meteorological indicators. Dated November 24, 1868.

The consists, first, in constructing thermometers with a vernier scale, by which the position of the mercury, or other fluid, is able to be ascertained, to the hundredth part of a degree, Centigrade, instead of to a tenth only, as heretofore.—Patent abandoned.

heretofore.—Patent abandoned.

3577 B. Hunt, Lincoln's Inn. Watches. (A communication.) Dated November 25, 1868.

This relates to a system of winding-up mechanism applicable to watches of all kinds, and by the aid of which the winding-up is performed in far less time and more easily than with any other system hitherto proposed or employed. The winder is formed by the back of the case itself, which is made movable, and acts on the ratchet of the barrel, which in this case is brought to the centre of the watch.—Patent abandoned.

3578 J. PARRY, Manchester. Springs for mattresses, &c ated November 25, 1868.

Dated November 25, 1868.
This consists chiefly in protecting the top of the spring by means of a top or cap of wood, metal, or other suitable substance, which top or cap is made preferably of a mushroom form, but it may be made oval, octagonal, or of other convenient shape.—Patent completed.

missircom form, but it may be made oval, octagonal, or of other convenient shape.—Patent completed.

3579 R. Lakin and W. H. Rhodes, Manchester. Spinning and doubling. Dated November 25, 1868.

This consists, first, in connecting the under faller and lever and brake lever, used for regulating the winding on by means of a spring instead of a chain. Second, in attaching the tension pulley on the headstock, used for tightening the rim band to one end of a lever, and applying a spring at the other end of the lever, to exert a force on the band, in order to produce the degree of tension necessary to ensure more regular turning of the spindles. Third, in hinging to the faller leg an elbow lever mounted on the stud, the lower end of which is connected with the faller leg. The object of the fourth improvement is to prevent the breakages which sometimes occur when the mule fails to make the change required to put the clutch box in connection with the back or drawing out shaft out of gear. To accomplish this the stude of one or more of the wheels, which are used for drawing out the carriage, are attached to the lever instead of to the frame side, as now customary.—Patent completed.

3580 W. WILD, Oldham. Driving shafts. Dated Novem

3580 W. WILD, Oldham. Driving shafts. Dated Novemer 25, 1868.

3530 W. Will, Oldham. Driving majis. Descend normalist 25, 1868.

The invention is designed for the purpose of equalizing and regulating the speed motion or velocity of revolving shafts, spinnles, and other machinery, by an adaptation thereto of a compensating movement, by which the time and speed of connected parts is provided for in such a manner that the resultant motion is entirely freed from "back lash."—Patent abandoned.

3581 G. BERNHARDT, Radcliffe. Regulating supply of gas

3581 G. BERNHARDT, Radcliffe. Regulating supply of gas Dated November 25, 1368.

This consists in arrangements and apparatus which will open a valve or tap to turn on the full pressure and supply of gas, when the driving power in a manufactory is set to work, and to shut the valve or tap, or turn off the full pressure and supply of gas when the driving power ceases to work. The invention may be carried into effect by various arrangements, but that which is preferred is an ordinary ball governor, given by or geared with some convenient shaft. The action of the governor, when it rotates, opens the valves, and when it ceases to rotate it closes the valves, which (if a lifting valve) is connected with the governor through an ordinary water or mercury sealed slide. The minimum supply of gas to allow of small lights, before the driving power begins, and after it ceases, may be allowed to pass through a small hole adjusted by a screw plug, or through a small tap.—Patent completed.

3582 T. CRAIG. Lincoln's Inn. Handing windows. Ar.

completed.

3582 T. Craffe, Lincoln's Inn. Hanging windows, &c. Dated November 25, 1868.

This consists in cutting a groove in one or both sides of either the sash or frame of the window or other fittings, to any required depth or width, and inserting therein one or more loose or detached rollers or wheels of indis-rubber, or other suitable elastic substance or compound of any required dimensions, which rollers, when the window sash is in its place in the frame, are, to a certain extent, compressed, thereby creating sufficient friction to maintain the

said sash in any position to which it may be adjusted, while, at the same time, the said rollers are free to roll in either direction to allow the sash to be easily moved. In raising or lowering the sashes, the rollers or wheels revolve, and travel within the groove for a distance proportioned to that traversed by the sash, and regain their original position when the sash is shut, either up or down, as the cuse may be. To facilitate the raising of the windows when they are of any considerable weight, it is intended to affix cords, working in pulleys, inserted in the top of the frames, one for each sash, similar to the cords of Venetian blinds. These rollers can be adapted to the windows of railway carriages, or of any other structure. or venetian blinds. These rollers can be adapted to the windows of railway carriages, or of any other structure—Patent completed.

-Fatent completed.

3583 P. SPENCER. Nowcastle-upon-Tyne. Preparing indigo blue Dated November 25, 1863.

This consists in spreading the indigo upon sheets of paper, linen, calico, or other like material instead of making it up into balls or "thumbs," as heretofore. In making use of the indigo thus prepared or made up. a slip of the sheet is cut off and put in the water.—Patent abandoned.

of the sheet is cut off and put in the water.—Patent abandoned.

3584 W. R. LAKE, Chancery-lane. Manutacturing cigars. (A communication). Dated November 25, 1868.

This consists in the general construction of the machine, and more particularly in the application, form, and arrangement of a number of non-elastic rollers, between which the cigar is formed, and in the use of a follower, to prevent the cigar from being too long, of a header for forming a point, and of a cutter for cutting and trimming the thick end of the cigar.—Patent completed.

3585 S. Brook and C. Thompson, Halifax. Looms. Dated November 25, 1868.

This relates to means of acting upon the "swell" in looms for weaving, so as not to press upon the shuttle any time, except immediately after the shuttle has got into the box, and which is relieved again before the shuttle is picked or sent out of the box. This is effected by means of a lever hinged to the loom end, and extending over or under the crank shaft, and also under the lathe or going part of the loom. A bracket with a friction roller is fixed on the stop rod, and can is fixed on the crank shaft, which, as the said shaft rotates, acts upon the lever, and through it on the stop rod, and, consequently, on the swell in like manner.—Patent completed.

3586 D. S. Merry, Hackney. Arm protectors. Dated

8586 D. S. MERRY, Hackney. Arm protectors. Dated November 25, 1868.

The inventor forms a covering for the arm of leather The inventor forms a covering for the arm of leather or other suitable waterproof or fireproof material or combination of materials, to fit closely round the wrist by means of an elastic gusset, or by buttons, hooks buckles, or other suitable means applied at that part. These protectors may extend from the elbow to the wrist, or they may be made long enough to protect the arm from the shoulder downwards to the wrist; in which case, when made of rigid or comparatively rigid material, it will be made in two parts, connected together at the elbow by means of a suitable elastic or flexible tube or connection.—Patent abandoned.

2357 W. F. Chapman Llandudgo, Packing case, Datad.

—Patent abandoned.

3537 W. F. CHAPMAN, Llandudno. Packing cass. Dated November 25, 1868.

The inventor makes a series of trays or shallow boxes, open at top, which, when piled one upon another, form a package resembling an ordinary packing case. The bottom tray is provided with a vertical rod at either end fixed firmly outside the tray. The said rods are of a length equal to the depth of the series of trays combined together, and the tops of the said rods are screwed and are provided with screw nuts. Each of the other trays is provided at each end with an eye or loop, through which eyes or loops, when the trays are piled upon one another, the rods fixed to the bottom tray pass.—Patent abandoned.
3538 G. BAKKE, iun. Birmingham. Birmleans. Dated

eyes or loops, when the trays are piled upon one another, the rods fixed to the bottom tray pass. —Patent abandoned.

3588 G. Baker. jun., Birmingham. Bird cage. Dated November 25, 1868.

This consists, first, in making the bases or bottoms of bird and other cages of papier mache. These bottoms are made, by preference, of a disc of a larger diameter than the cage. This disc has a raised concentric ring or rim of somewhat less diameter than the body of the cage. The body of the cage is dropped around and secured to the ring or rim in the following manner:—On one side of the ring or rim in the following manner:—On one side of the ring or rim and at a short distance apart, one or two small metallic tongues are fixed, and opposite the said tongues is aspring catch fastening. In a ttaching the body of the cage to the bottom, one side of the metal band at the bottom of the body is inserted under the tongues, and the opposite side of the said band is passed into the spring catch fastening. In this way the body of the cage is secured around the rim of the bottom. In order to liberate the body from the bottom, the movable part of the spring catch fastening is pulled by the thumb and finger when the body becomes detached from the bottom. The method of fastening described may be applied to cages having bottoms of metal or other hard material, the bottoms having the raised rim or ring described with reference to papier mache bottoms.—Patent completed. or ring described with reference to papier mache bottoms Patent completed.

—Patent completed.

3599 W. E. Gedeg, Strand. Tug boat. (A communication). Dated November 25, 1868.

An endless chain or iron wire cable thrown into the watercourse along the whole line to be worked, and fixed only at the up-stream end, serves as fulcrum to the travelling tag resisting the traction of this latter by its weight alone. Thus the most powerful tugs may be attached to it at a distance from each other of less than 1,094 yards (I kilometer), and mount the stream without those up stream being in any way hindered by the traction or pulling of those belowat the bends. Movable guilets keep the fulcrum in the centre of the breadth of the stream.

—Patent abandoned.

Patent abandoned.

3590 W. E. Geder, Strand. Sweing machines. (A communication). Dated November 25, 1868.

In making embroidery work on a sewing or embroidery machine, the great difficulty occurs in making curves, circles, or other intricate design, the entire cloth has to be turned constantly in conformity with the design to be unded, and for this reason that description of embroidery work is not only difficult to execute but can be executed with a very moderate degree of speed only. To avoid this difficulty, the inventor has combined the several working parts of an embroidery machine in such a manner that a universal feed motion causes the cloth to move in any desired direction, and that the hooks or needles which make the stitch move in combination with said feed motion, so as not to change their relative positions to each other; thus embroidery work of the most intricate design

can be made without turning the cloth.—Patent com-

3591 H. SMITH. Westbourne-terrace-road, W. Playing

3591 H. SMITH, Westbourne-terrace-road, W. Playing games. Dated November 25, 1868.

A block of a polygonal form is employed, and it is padded round the edges with vulcanized india-rubber or other clastic material. This block is adapted to stand in the centre of a circular or other table, and it may support a lamp to throw on to the table the uniform light which the game requires. The surface of the table is covered with a woollen cloth having a circle marked upon it, which may conveniently be from 3ft, to 4ft, in diameter, and this circle is divided up into as many equal segments as there are sides to the block.—Patent abandoned.

and this circle is divided up into as many equal segments as there are sides to the block.—Patent abandoned.

3592 E. T. VAN HECKE, Courbevoie, Paris. Steam boilers, Dated November 25, 1808.

The boiler is formed of cylindrical plates of metal with a dome-shaped top or steam chest. The firelox is also cylindrical with a dome-shaped top, and the bottom of the boiler and flrebox rest upon and are affixed to an annular flat plate of metal with water space between the two. A series of tubes extend from the top of the flrebox to the top of the boiler, to which parts the tubes are fixed watertight by their ends. The inventor surrounds the boiler with a jacket of metal for a portable or locomotive boiler, and with brickwork for a stationary or fixed boiler, the space between the boiler and jacket being for the passage of the heat, gases, and smoke from the furnace fire, and on a line with the bottom of the boiler and firebox, and in a line with the bottom of the boiler and firebox and in a line with the bottom of the boiler and firebox and in a line with the bottom of the boiler and firebox and in a line with the bottom of the boiler and firebox and in a line with the bottom of the boiler and firebox and in a line with the bottom of the boiler and firebox and in a fire with the bottom of the boiler and firebox and in a fire with a firebox and in a line with the top of the boiler. He forms two short horizontal flues leading from the flue that surrounds the boiler should be affixed the firebox and in a line with the top of the boiler. He forms two short horizontal flues leading from the flue that surrounds the boiler should be affixed to the formation of the boiler.

State of the firebox and the firebox and the boiler and the boiler and the boiler.

Patent completed.

Patent completed.

3593 N. D. SPARTALI, Liverpool. Heating boilers. Dated November 25, 1863.

This relates chiefly to the economic and efficient application of liquid hydrocarbon as a fuel for heating steam boilers, whether marine, stationary, or locomotive. In adapting the invention to marine boilers, as at present constructed, the inventor applies to the fire chambers or furnace a cylindrical auxiliary or supplementary boiler with one or more longitudinal fire flues passing through it, and he supplies liquid fuel to the fire flues (in which it is ignited) to heat the same in the following manner:—The liquid fuel is forced (in the form of spray) into the fire flues by high pressure steam or heated air admitted to the feed pipe in rear of the mouth or discharged end. Air may also be admitted direct to the fire flue to fan the flame of the ignited fuel and increase its intensity if required.—Patent completed.

3594 J. BUENNE. Leith, North Britain. Production of

required.—Patent completed.

3:594 J. BOURNE, Leith, North Britain. Production of heat and motive power. Dated November 25, 1868.

The inventor produces motive power by means of the heat derived from combustibles, as is done in the steam engine. But he generates the heat in a different way from that adopted in the case of the steam engine, and he transforms the heat into motive power by a method not heretofore in use, and with a smaller consumption of fuel than by any method yet practised. Patent completed.

than by any method yet practised —Patent completed.
3595 H. MILSTED, City-road, Buckles. Dated November 25, 1868.
This buckle consists of two parts combined, that is to say, the sides or lateral arms of the frame of the buckle instead of being, as is usual, each a solid or continuous piece, are spring arms or sides, that is to say, each such side consists of a rod, bar, or arm entering a hollow or tubular rod, bar, or arm, and used in combination with a spring. The tubular arms are capable of sliding on or over the inner arms, or the inner arms of sliding in the tubular arms.—Patent abandoned.

2596 W. R. Lake, Chapperylane, Statistics, 14 com-

over the inner arms, or the inner arms of stiding in the tubular arms.—Patent abandoned.

3596 W. R. Lake, Chancery-lane. Sad irons. (A communication). Dated November 25, 1868.

This consists, first, in the combination with a reversible sad iron, provided with a suitable burner, of a reservoir for containing oil or other hydrocarbon liquid so connected to the sad iron as to supply the burner with the necessary quantity of the oil or other hydrocarbon liquid. Also, in the combination with the r servoir and sad iron of devices or mechanism for heating the iron by generating and burning within the same the vaporous products of the oil or other hydrocarbon liquid. Also, in a burner of novel construction, with which is combined a vapour generating chamber. Also, in the arrangement of a valve and means for operating the same, whereby the flow of the hydrocarbon liquid may be regulated as desired. Also in constructing the inner surfaces of the smoothing plates of the iron with radial corrugations, whereby a more uniform heating of the smoothing plates of the iron is effected.—Patent completed.

3597 D. Vogl. Basinghall-street. Fustening scarres. (A

3597 D. Vool, Basinghall-street. Fastening scarres. (Acommunication). Dated November 25, 1868.

3597 D. Vool., Basinghall-street. Fistening scarres. (A communication). Dated November 25, 1868.

The inventor uses an appliance consisting of two bars or plates. One of these bars or plates, which he calls the working plate, is suspended or jointed to, or mounted in the other. This bar or plate has projecting parts at the ends of its upper edge on each side, which projections engage and work in bearings formed by, or in, bent up or projecting parts formed at the corresponding part of the other plate or bar.—Patent abandoned.

other plate or bar.—Patent abandoned.

3598 E. ELLENBAND, Manchester. Needles. (A communication). Dated November 25, 1868.

This consists of a metallic tip containing passages at right angles to one another, into one of which the needle to be threaded is inserted with its eye downwards, and through the other (which is enlarged at its mouth to allow it to enter easily) the thread is pushed in the same way as threading a needle, the only difference being that, instead of having to pass the thread through a minute hole, it is pushed into a funnel-shaped passage, and such is the peculiar action of the hole so formed that the thread causes the needle to assume the proper position to allow the thread to pass through its eye and out at the other extremity of the hole. This done, the needle is pulled out, and the thread follows it through the same hole, when the needle will be found to be threaded and ready for use. needle will be found to be threaded and ready for use. Patent abandoned.

3599 L. ROMAN, Paris. Hydraulic motive power. Dated

November 26, 1868.

November 26, 1868.

This consists in two endless chains formed of bars of flat iron, with articulated joints and curved paddles fixed on these bars. These paddless are kept perpendicular and parallel to each other at suitable distances apart, so as to

form an endless chain of paddles, which chain is laid over form an endless chain of paddles, which chain is laid over two or more drams, pulleys or wheels, the ares of which are situate parallel to the level of the water, and revolve in vertical stundards provided in boats or other suitable movable or fixed supports; the said endless chain is laid in the direction of the current, and kept at such height that the paddles of the lower portion of the chain are immersed perpendicularly in the water, whilst the remain-der of them are out of this latter.—Patent abandoned.

immersed perpendicularly in the water, whilst the remainder of them are out of this latter.—Patent abandoned.

3600 F. Holl, Gorton. Steam engines. Dated November 26, 1863.

The object is to reduce the friction in the working surface of steamengines of an improve I lubricating apparatus, and to prevent the escape of steam in the stuffing boxes, by means of an improved metallic packing. The lubricator consists of a vessel provided above and below with a valve seating. The spindle of the upper valve is serewed into the spindle of the lower valve, and the upper and lower valves, and are held upagainst their seatings by the spring which abuts against the fixed washer and the loose washer placed below the boss of the hand wheel fixed to the spindle. The upper valve is opened to pour the lubricant into the vessel, by screwing the upper into the lower rapindle, and it is closed by turning the spindle in the contrary direction. When the cylinder or other part requires to be lubricated, the lower valve is opened by turning the upper spindle, to allow a portion of the lubricant to flow out of the vessel, through the elbow plps, the upper part of the spindle, which is made with diagonal perforations to convey the lubricant into the pipe. The quantity of lubricant allowed to escape is governed by the diameter of the shoulder on the spindle passing through the opening above the seating —Patent completed.

3601 P. BANTON, Craven-hill, W. Firearms. Dated November 26

the seating —Patent completed.

3801 P. Banton, Craven-hill, W. Firearms. Dated November 26, 1868.

The object is to effect the ignition of the charge by friction instead of by percussion. The inventor prepares cartridges with nipples charged with matter which is readily ignited by friction, such as the mixtures ordinarily employed for lucifer matches. In the lock of the arm to which the invention is applied, instead of the hammer ordinarily employed for striking a percussion cap, a stiding piece is used, which can be pulled back by hand, and which is urged forward by a spring. This sliding piece has notches into which a detent, connected with the trigger, engages, so as to hold it back until the indent is released, by pulling the trigger, in which case the spring causes it to slide forward.

—Patent abandoned.

2602 A. M. CLARK, Chancery-lane. Sizing threads. (A communication). Dated November 26, 1868.

This consists in a preparation formed by the combination or mixture of the following substances in about the following substances in a substance in the following substances in the following substances in a substance in a substan or mixture of the following substances in about the following proportions:—Gelatine, 13lb.; dextrine, 8.lb.; sulphate of lime, 1lb.; glycorine, 110lb.; chloride of calcium, 1;0z.; spermaceti, 1lb.; phenic acid, 1;0z.; caustic sods, 3oz.; syrup of fecula, 11lb.; stearine, 4;lb.; starch, 12lb.—Patent completed.

3603 J. Sincock, Birmingham. Ratchet braces. Dated November 26, 1868.

This consists in the employment of a sliding pawl acted

This consists in the employment of a sliding pawl acted upon by a belieal spring, enclosed in a spring box, for actuating the ratchet wheel of a ratchet brace or lever. The shiding pawl, spring, and spring box (which latter may be provided with a screwed cap or cover, for the facility of removing the pall and springs), are all contained in the head of the actuating lever of the brace, and access to the ratchet wheel can be obtained by removing the hoop or bush which serves to keep the ratchet wheel in its place. This hoop is held in its place by two or more screws, on removing which all the parts can be readily taken out—Patent completed.

3604 H. SWITHENBARK LAWFERCE-lane. Manufacture of

Patent completed.

3604 H. SWITHENBANK, Lawrence-lane. Manufacture of hats. (A communication). Dated November 26, 1868. The inventor makes the potence receive, in addition to a half block, which is held stationary, whilst in use, a whole block which can be turned round whilst the hat is upon it, so as to expose every part of the hat in turn to the iron, or it may be the brush which is being used. In place of fixing the rectangular projection rigidly to the standard, as heretofore, he arranges it to turn upon a joint, so that instead of projecting to the front, as it does when in use, and when the half block is upon it, it can be turned to the back, out of the way, and he also mounts similarly on the same standard a stud or pin which is turned to the front when the whole block is to be used, so as to stand out horizontally from the front of the standard.—Patent abanhorizontally from the front of the standard.-Patent aban

doned.

3605 G. E. SPOONER and G. A. HADDART, Bron y Garth, Carnarvon. Rathways. Dated November 26, 1868.

The abutting ends of the rails, whether they be double headed or formed with a flat base, the inventors propose to clip between two plates, suitably shaped to embrace the web, and the foot or lower head of the rail, and by preference to extend vertically a sufficient distance below the rail to admit of being pierced to receive clamping boits. The plates they secure like ordinary fish plates to the rails, by passing boits through them and through the webs of the rails and by the additional bolts below the base of the rails, the coupled ends are held as in a vice; the vertical continuation of the plates below, the rails are made of a sufficient depth to act as an under girder or plate to stiffen the joint.—Patent abandoned.

3606 A. Busche, Schwelm. Making laces and braids.

mepta to act as an under girder or plate to stinen the joint.

—Patent abandoned.

3606 A. Busche, Schwelm. Making laces and braids.
Dated November 26, 1838.

This consists in an improved arrangement of the carriers, for enabling the machines to occupy much less space than those at present in use. Instead of placing all the car, iers in one concentric circle, as hitherto, the inventor divides the gross number into two unequal numbers. In the larger of these numbers, two of the carriers are drivers, their pinions being geared into a driving toothed wheel. The pinions of the drivers gear into the pinions of two other carriers, and the pinions of the hatter into two others, and so on, continuing in a concentric circle. The remaining number of carriers are placed in pairs in a concentric circle around the inner series, and the pinions of each pair gear into the pinions of two of the inner carriers. The two driver carriers revolve in the same direction, and all the other carriers revolve in opposite directions to each other, as in the old machines.—Patent completed.

3607 E. T. Hughes, Chancery-lane. Dessing stone. (A communication). Dated November 26, 1888.

This consists in placing the stone or other substance on

3607 E. T. HUGHES, Changes, communication). Dated November 26, 1868.
This consists in placing the stone or other substance on a movable platform or turntable, and causing a suitable tool to revolve against the edge or surface required to be dressed.—Patent completed.

3608 H. POLLACK, Hamburg. Breech-loaders. Dated

3603 H. POLLACK, Hamburg, Breech-loaders. Dated November 26, 1868.

This consists in securing to the stock of the gun by a screw, a metal pipe having at the topan indented opening, and at the fore end an internal screw, to which the barrel is screwed, either with or without a seating. In this pipe is placed a metal cylinder, open at the back, but having outside the hole a projecting cam, to be used as a presser, and at the other end the cylinder carries the locker, which consists of a flat head in contact with an india-rubber washer, between which and the end of the cylinder there is a layer of leather. The head is formed on a screwed pin having a hole in the centre for the needle to pass through, and the pin is fixed to the cylinder from the inside, by means of a screw nut, there being a long key adapted for the purpose, and the inside of the cylinder is cleaned by a chamber cleaner when required.—Patent completed.

3609 W. R. Lake, Chancery-lane. Paddle wheels. (A

by a chamber cleaner when required.—Patent completed.

3609 W. R. LAKE, Chancery-lane. Paddle wheels. (A communication). Dated November 26, 1868.

This consists in pivoting the blades of paddle-wheels in the centre of their width, so that they can freely turn to accommodate themselves to such position as will offer the least resistance to their entrance into the water, and, as soon as submerged, assume and maintain the perpendicular position until the wheel in its revolution raises the urper edge out of the water. The blade will then directly assume the best possible position to pass up out of the water with the least resistance, viz., an incline, so that it raises no water, and, consequently, there is no loss of power. One method of carrying this invention into effect is to have the convex side of the blade, or that part that is below the axial line, forward, so that the convex curvature will be in advance of the terminus of the curve at the lower edge of the blade, and the upper wing of the blade will have the concave side forward, and the result will be that when completely submerged, the blade will assume the perpendicular position, and keep such position as long as it is so submerged.—Patent completed.

3610 W. R. LAKE, Chancery-lane. Harvesting machines.

dicular position, and keep such position as long as it is so submerged.—Patent completed.

3610 W. R. Lake, Chancery-lane. Harresting machines.
(A communication.) Dated November 26, 1868.

These machines are constructed with a toothed wheel, disc, or head, supported by its hub on a stem or post, which is continuously revolved when the machine is in motion by a pinion fixed on the shaft, which is turned or driven from the main carrying and driving wheel by or through the toothed wheel, which meshes with a pinion on the end of another shaft, and thus drives it. The opposite end of this last shaft has a bevel wheel upon it, which works on a bevel wheel on the shaft, which is thus driven, and, in turn, drives the wheel disc, or head. In bearings upon the wheel, but remote from its centre, are hung crossed axles, which are bent at their line of crossing, so that they may pass each other, and still revolve, though hung in the same plane. Upon these cross shafts are journals, set at right angles to each other, or nearly so, and also remote from the centre of the wheel, and upon these journals the hubs of the rake or reel arms are placed, and they revolve with them, and at the same time they can roll upon them, to make them act as rakes or beaters at the will of the operator, who rides on the machine. Upon each of the hubs there are three studs or projections. There is also a slot in each hub, through which a pln passes into its journal, and which pin and slot define the extent of the rolling motion of the rakes or beaters, whilst the lugs, studs, or projections citer aid in turning the rakes or beaters or prevent their turning, as the case may be.—Patent completed.

3611 J. H. Morrian, Belfast, and J. Coulong, Blackburn. Paymantic lown.

either aid in turning the rakes or beaters or prevent their turning, as the case may be.—Patent completed.

3611 J. H. Moreland, Belfast, and J. Coulong, Blackburn. Preumatic tooms. Dated November 26, 1863.

This relates, first, to an improved mode of constructing the shuttle boxes of pneumatic looms, the object being to render them more perfectly airtight, while they offer less friction to the shuttle on its entrance and exit than heretofore. To this end, the inventors line the shuttle boxes with corkwood of about one-quarter of an inch in thickness, and extend the lining for about two-thirds the length of the shuttle. The boxes may be formed outwardly of wood or iron, and fastened to a slay in the usual manner. If the boxes be of wood, the patentees fit wrought iron straps, on having set screws on the front and top sides, for contracting the diameter of the box, to compensate for the diminution of size of the shuttle by friction in working. The invention relates, second, to a novel mode of obtaining the pick in pneumatic looms. This object is attained by fitting on each end of the crank shaft an additional crank or eccentric of about the same throw as the crank used for working the slay, and fitting on the back of the slay, at or near the ends thereof, two light metallic cylinders, which communicate with the shuttle boxes, and in which work pistons, connected respectively to the cranks or eccentrics on the crank shaft ends. These pistons and cylinders act like air pumps, and thus impart the required reciprocating motion to the shuttle.—Patent completed.

3612 A. Harris, Thame. Warming buildings. Dated

3612 A. HARRIS, Thame. Warming buildings. Dated

November 26, 1868.

This apparatus consists of a firebox with an ashpit. From the top of the firebox a quantity of round, square, or any other shaped pipes, varying in number from three and upwards, terminating in a smokebox, whonce they proceed into a chimney. The external cold air is introduced by a pipe or air passage, leading into the ashpit to the fire, up through the smoke pipes, into the smokebox, and up the chimney, and can be stopped off by valve at pleasure. The air is conducted from the most extended and coldest parts of a building, through pipes or air passages, regulated by ventilators or gratings into an air chamber, formed in the lowest portion, passing through openings into a space forming the exterior of the firebox, circulating round the same and between the pipes. It then passes out at the top or sides of the apparatus, through apertures or gratings into the building, causing a continual circulation of hot air throughout the building. Cold air is likewise supplied the at bottom of outer casing through the pipe, for ventilation, and is stopped off by a valve at pleasure. At the top of the smokebox is a vessel, in which water is placed, by the evaporation of gratings.—Patent completed.

3613 E. STEVENS, Islington. Sharpening knices. Dated

vessel, in which water is placed, by the evaporation of which the hot air is moistened before passing out through gratiugs.—Patent completed.

3613 E. STEVENS, Islington. Sharpening knires. Dated November 27, 1868.

This consists, in the first place, in the forming, employment, and mounting of solid cones and not hollow or drilled through, to be fixed by screws, rivets, or otherwise.

These solid cones are formed smooth, fluted, grooved, or rough, and equal in shape, size, or circumference. The

inventor fixes the solid cones on suitable thin flat top and bottom plates. He makes a hole of the bottom plate, into which bpin or screw.—Patent completed. he inserts a flat-headed

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed. NOTICE.—Having received communications from person

Science and Art.—A striking instance he immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmalsing, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brooches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[ADVT.]

#### COCKER BROTHERS

C C K E R B R O T H E R S (Successors to Samuel Cocker and Son),
SHEFFIELD.

SHEFFIELD.

ESTABLISHED 1792.

MANUFACTURERS OF STEEL FILES AND WIRE; Als of
"COCKER'S" PATENT STEEL ROPE WIRE

In long lengths, from 101b. to 40th. pieces, without welding, and capable of bearing as high a breaking strain as any in the market. Each piece warranted to twist round its own diameter.

Three First-Class PRIZE MEDALS were awarded to SAMUEL COCKER and SON, Sheffield, at the Great Exhibition of Industry, London, 1831.

First-class PRIZE MEDAL was awarded to COCKER BROTHERS at the Universal Exhibition of Industry, Paris, 1855, and MEDAL of HONOUK awarded to COCKER BROTHERS at the Universal Exhibition of Industry, Paris, 1855, and MEDAL of HONOUK awarded to COCKER BROTHERS, by the Society of Arts and Industry, London, 1856.

### MULLINER, COACHBUILDER, LEAMINGTON SPA, AND 24, BAKER-STREET, LONDON.

Carriages of every description on View, especially the

PARIS PRIZE MEDAL HICKORY PHAETONS

WM. WARNE & Co., 9, Gresham-street West, E.C., and Tottenham, N. A 3

#### COLLINGE'S

PATENT SPONGE CLOTHS
For cleaning steam engines, machinery of every description, lamps,
windows, &c., &c. Being a woven fabric, they are easily washed,
say, twenty times; consequently, do not cost one-fourth the price of
cleaning waste. Trade allowance made to dealers, factors, and agents. Samples and prices upon application to

DANIEL COLLINGE AND SON, 1, PEEL STREET, MANCHESTER. B 17

#### THOMAS TURTON AND SONS,

Manufacturers of

CAST STEEL for Cutters, Punches, Taps, and

CAST STEEL Piston Rods, Crank Pins, Connecting Rods, Straight and Crank Axles, Shafts, and Forgings of

other make. (See results of trial in the "Times," July 26, 1851.) TOOLS of all kinds for Engineers, Railways, Con-

EDGE TOOLS, marked WM. GREAVES and 80NS. Electro-Boracic Steel, warranted to wear out three Tools made of Cast Steel.

DOUBLE SHEAR STEEL, | SPRING STEEL, BLISTER STEEL, | GERMAN STEEL BLISTER STEEL SPRINGS, BUFFERS, and CAST STEEL TYRES

For Locomotive Engines, Railway Carriages, and Waggons.

SHEAF WORKS and SPRING WORKS,
SHEFFIELD.
London Warehouse: 35, QUEEN-STREET, CITT,
Where the Larger Stock of Steel, Files, Tools, &c., &c., may be
selected from.

JUST PUBLISHED.

#### BAILEY'S ILLUSTRATED INVENTIONS.

1869 Edition, 300 Engravings, free by post, 8 stamps. Of interest to everybody.

J. BAILEY & CO.,

ALBION WORKS, SALFORD,

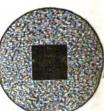

THE SILVERTOWN

#### ELASTIC LUBRICATED STEAM PACKING.

(Lubricated Cotton, with India-rubber Core)

ELEVATION. SECTION.

This Packing is far superior to any other kind made. It is already lubricated and ready to put in its place. It lasts a much longer time than any other packing now in use, and requires oiling but once per day, thus effecting an immense saving in the cost of oil and labour.

It can be worked either with or without oil or grease; but it is recommended to lubricate it once per day, which will keep the gland perfectly steam-tight, and the rod bright and clean.

Price 2s. 6d. per lb.

Made in lengths of 20 feet and upwards.

THE INDIA RUBBER. GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY, LIMITED.

WORKS :- SILVERTOWN, ESSEX.

Warehouse:-100, CANNON STREET, LONDON.

Notice.-All Orders should be ad

to the Works.

WHEEL, RACK, and SCREW CUTTING
SPUR, BEVEL, RATCHET, WORM, and INTERNAL
WHEELS cut to any size or number of teeth also racks of any length
or pitch. Dividing plates drilled or lined. Screws cut to any size o
pttch. J. Wilkinson.Engineer, 8t. George's Works, 42, late 83, 8t
George's-road, S.E., London.

The Medical Profession for thirty years have approved of this pure Solution of Magnesia as the best remedy for Acidity of the Stomach, Heartburn, Healtache, Gout, and Indigestion: and as the best mild aperient for delicate constitutions, especially adapted for Ladies, Children, and Infants.

DINNEFORD AND Co., CHEMISTS, 172, New Bond-street, London, And of all other chemists throughout the world.

TACHES, EYEBROWS, and a FINE HEAD of HAIR—A retired apothecary, from Wales, will send his noted FORMULA for 13 stamps and stamp-directed envelope, to produce Hair on the Head, Whiskers and Moustaches on the Face in three weeks.—MR. EVAN EVANS, M.D., C.M., Dorking, Surrey.

LADIES and GENTLEMEN, having a connection, may hear of an AGENCY that will add to their income from £3 to £5 per month. Address (enclosing stamped envelope), James Jefffelson, Eag., Forest Hill, London, S.E.

#### MECHANICS' MAGAZINE.

LONDON: FRIDAY, JUNE 19, 1869.

#### COLLIERY EXPLOSIONS.

THE immediate cause of the recent catastrophe at the Ferndale Colliery has not been the uncertain subject of speculation that such matters so frequently are; it was discovered at an early stage of the search. One of the victims, with that unfortunate disregard of danger to which those who follow highly hazardous occupations are so liable, wished to have a pipe over his work. The pipe, the tobacco box, and the opened lamp, showed that he was bent upon indulging in his wish at all risks. But before his purpose could be accomplished, his foolhardiness had cost him his life, and had sent his fellow workmen by scores into eternity.

And this is no new picture—the same tale has been told many a time and oft before, and may even have to be told again and again. The first thing that naturally occurs to everyone reading a description of the catastrophe is, Why are not miners' lamps provided with such fastenings as that the man cannot open them without destroying or damaging the lamps? We answer that means have been found—and excellent means, too-for securely locking miners' lamps, and for otherwise rendering them safe. There is the lamp of Mr. Story Horn, described and illustrated in the MECHANICS' MAGAZINE for April 9 last, and there is also the safety lamp of Mr. Gray, which appeared in our issue for the 30th of the same month. But. as a means of fastening the lamp safely and securely against the miner, the plan of Mr. S. P. Bidder, jun., described in our last number, must, we think, carry off the palm. Mr. Bidder has a spring bolt in the bottom of the lamp, which, when the bottom is screwed on to the upper part, shoots into a chamber in the upper frame, and the lamp cannot be unscrewed until the bolt is withdrawn. As it is held up by a spring, and as there is no access to it, this would at first appear an impossibility. Not so, however, when a powerful electro-magnet is applied under the lamp, directly beneath the spring. The electro-magnet being kept in the lamp room, and being of too expensive a character to be indulged by the miner, he cannot open his lamp otherwise than at the proper time and place. This method of locking miners' lamps was practically demonstrated at the recent conversazione of the Institution of Civil Engineers, and the principle is being applied to the whole of the lamps at the Harecastle Collieries, in Staffordshire.

Here, then, we appear to have the means of perfect immunity from the fearful explosions which have of late taken place with fatal continuity. But we fear that the most perfect system will not prove a perfect remedy, inasmuch as the man who would open his lamp would not hesitate, when that was utterly closed against him, to use a lucifer match or any other means of obtaining a light. With the devices we have mentioned, a colliery may be comparatively secure, but it cannot be absolutely safe so long as the men show an utter disregard to all rules and an indifference to their own and their comrades' safety. This, then, brings us to look at the other side of the question, and to inquire whether, as prevention is so greatly to be preferred to cure, there is nothing left undone that could be done, which would conduce to the safety of collieries, irrespective of locking safety lamps and other devices. And here we think there is much for which mining engineers must be held respond of the widows and orphans of their late comacter a clear saving of 35min. in time and 5d. in sible. How does it happen that a number of rades. But, no; the only accounts we observe expense; besides which—and this is of the

men are working, probably in fancied security, and then all at once are enveloped in the explosion, as it were, of a powder magazine? Let one of their number answer the question. In a short but highly suggestive letter in the "Times," of Tuesday, Mr. George Fowler, writing from Hucknall Colliery, Notts, observes that the only parts of the mine in which any attempt is now made to ventilate are the working roads and faces; the goaves, or places where the coal has been got, being left to take care of themselves. It thus happens, therefore, if a shot be fired, or any other vibration be imparted to the air, that the highly elastic gas lying in the crevices of the goaf expands, and if a naked light be present, an explosion is the consequence. The same writer asserts that there are many mines in work in which a man dare not for his life's sake carry a naked candle, and challenges a denial of his statement. There are many mines wholly de-pendent for their safety on the lamps and the caution of the men who use them. Unctionably, this is not as it should be. Unquesnormal condition of a mine should be perfect freedom from gas, and until this is brought about there is no reasonable hope of the is wanted, then, is a strong preventive measure in this direction. If there be no accumulation of gas, there can, except in the rare case of "blowers," be no explosion. With these facts staring us in the face, it is time to look to higher intelligence to prevent these disasters by removing from the careless, the ignorant, or the foolbardy, the means whereby they may, however unintentionally, practically commit suicide, and slaughter their fellow creatures by wholesale.

In the meantime, however, and until min-ing engineers have devised means for preventing such a condition of things in the workings, as is represented by Mr. George Fowler, it is still our duty to insist upon the adoption of such preventive measures as are ready to hand. And even under improved systems of working, every precaution will still be necessary, inasmuch as coal mines are worked under conditions which, at the best, will always present features of risk. Hence, the systems of locking the miners' lamps, and of rendering them safe in other respects, to have alluded, will always, and which we under any circumstances, prove of the highest value and importance. Hence, also, stringent supervision should be enforced, and if men will not care for themselves, they should at least be made to feel that there are more lives than their own at stake. But what can the closest supervision effect, or what will the most rigid rules do, in the case of such a class of men as appears to be working at the Fern-dale Colliery? What can be said or done when we find that of those delivered from sudden death, there were none who were sober enough to carry the remains of their late mates to the grave, but that the coffins were borne by strangers? And what, when we find that one of the number who was brought up half dead to the pit's mouth, celebrates his deliverance by a drunken debauch? These are startling statements, but they are, never theless, veritable facts, which, we can only trust, would not find their parallel in any other mining community. It might reasonably have been supposed, that as pay-day followed so closely upon this accident, the men would one and all have devoted somewhat of their earnings to the alleviation of the distress thus suddenly brought upon so many dependent families. We will not go so far as to say that it might have been given as a thank-offering for their own safety, because we fear the majority of these men are hardly capable of realizing such a sentiment as gratitude for such a mercy. But they surely possess some spark of charity, which ought to have prompted them to consider the wants

of them, state that they have given themselves

up to a drunken revelry.

But to return to the practical point at issue —the prevention of these calamities—we will here take the opportunity of noticing another invention having this object. Mr. S. P. Bidder, jun.—the same gentleman to whose method of locking safety lamps we have referred-has invented a machine for breaking down coal without the use of gunpowder. A model of this machine was exhibited at the late conversazione at the Institution of Civil Engineers, and it was briefly referred to in our notice. We have since received the details of the apparatus, and think no time could be more fitting than the present for bringing the invention before the public. Mr. Bidder was led to the present invention by a knowledge of the impossibility of providing, in some cases, a perfect system of ventilation, and the danger of blasting with gunpowder. He, therefore, effects the breaking down of coal with an apparatus of which the following is a description:—There is first a small hydraulic press of 15 tons power, and which weighs about 1 cwt. Connected with the press, by a collar, is a pair of steel tension straps bent in the form of a tuning-fork. At the end of these straps is a clearance box, about 4in. long, and upon each side of the straps are steel expanding pieces, about 15in. in length, and which press against the sides of the hole. In working, the points of a pair of twin wedges, 15in. by 3in., which form one wedge, are inserted in the expanding piece, and the machine is fixed in the hole. The hydraulic press which is charged with about three pints of water, is then worked by a man, by means of a small handle, and the ram from the cylinder is forced out, thus driving up the pair of wedges between the expanding up the pair of wedges between the expanding pieces, giving a lateral extension of about 3in. This not being in all cases sufficient to bring down the coal, the press is withdrawn, and the relief-valve opened, thereby allowing the water to return to the reservoir, so that the same water is used over and over again. A second wedge is then inserted between the two twin wedges, and is driven home in the same way as before. By this means, an additional expansion of 3in. is obtained, making a total expansion of 6in., which, in most cases, is found sufficient. A third wedge can be applied, if necessary, and the expansion thus increased to the extent required.

The principal part of the machine is the drilling apparatus, and this consists of a 11-inch screw 4ft. long, and to the end of which is fixed the drill. A bar of iron is inserted in the coal at the side of the place selected for the hole which the machine has to drill, and this bar serves as a bearing for taking the resistance of the screw. A hole, 10in. deep and 1in. in diameter, is first punched with an ordinary tool, and in it the bar is inserted. The screw is then adjusted to the bar, and the drill driven in the coal by means of a handle at the end of the screw, which is turned by the operator. occupied in cutting the hole for the bar is occupied in cutting the noie for the bar is usually about 4min., and the time required for drilling a hole for the machine, 3ft. 6in. deep and 3in. diameter, is from 10min. to 15min., according to the hardness of the mineral. This apparatus has been practically tried, with highly satisfactory results, at a pit belonging to the North Staffordshire Coal and Iron Company, at [Talk of the Hill in a heading known as the Talk-o'-th'-Hill, in a heading known as the Eight-feet Banbury seam of coal, at a depth of 350 yards from the surface. Notwithstanding the disadvantages under which first trials of machines are usually conducted, the hole for the machine was drilled and about four tons of coal were brought down in 25min. According to the present system of blasting, an hour would have been required to drill a hole and fire a shot, which would take 1lb. of gunpowder, costing 5d. Here, then, we have

first importance—the work was done without the slightest danger. Other trials succeeded the one above recorded, the results being equally satisfactory. Mr. P. Higson, the Government inspector of mines for the district of South-West Lancashire and North Wales, was present at the trials, and we understand he has been instructed to report the result to the Home Secretary. If it can be shown that Mr. Bidder's machine effectually supersedes blasting with gunpowder, the Government will probably prohibit the use of powder in dangerous seams, and thus we shall have advanced one important step in the prevention of colliery explosions.

#### SHELL EXPERIMENTS AT DARTMOOR.

TN the wild and romantic regions of the Dartmoor Forest, Devon, and about a mile from the unromantic prison, a camp of some 300 men has lately been formed. The troops consist of the A battery of the C Brigade of Royal Horse Artillery, with six 9-pounder breech-loading Armstrong guns; the C battery of the 9th brigade of Royal Artillery, with six 12-pounder breech-loading Armstrong guns; and a battery of the 13th brigade of Royal Artillery to assist in placing the targets, throwing up earthworks, &c. This force is under the command of Colonel Saunders, and the object for which they are assembled is to test the relative practical values of shrapnel, segment, and common shells for rifled field artillery service. It has been the endeavour of the authorities to determine this by a series of experiments at Shoeburyness. But the character of the ground, which is a hard, flat, sandy plain, quite unfits it for the purpose, and the results have not been of any practical value. At Dartmoor, we have ground of an irregular and varying nature, presenting points resembling those which would be met with in actual service. Hence, the series of experiments which it is proposed to carry out there will determine what results are likely to be attained by artillery shell practice in hostile engagements. The committee appointed to conduct these experiments consists of Major General Dickson, V.C., C.B. (President), Colonel Elwyn, R.A., commandant and superintendent of experiments at Shoeburyness Colonel Romer, commanding Royal Artillery, Western District; Colonel Strange, C.B., R.H.A., Colonel Michell, C.B., R.H.A., Lieut.-Colonel Sladen, R.H.A., and Major Stirling, R.A. Captain Alderson, R.A., the assistant superintendent of Shoeburyness, is the secretary, and his Shoebury experience will prove invaluable to the committee.

The proceedings commenced on Wednesday last, but the practice was considered as preliminary only. The instructions directed the firing of segment, shrapnel, and common rifle shells over moderately broken ground, each half battery to fire five rounds per gun deliberately, using time and percussion fuzes in segment and common shells. Is is intended, in all experiments where the time and percussion fuzes are used in conjunction with each other, to burst the shell by the time fuze. A double line of targets has been erected at 1,300 yards range; they are 54ft. wide by 6ft. high. The trials commenced by the first half battery (A) of three 9-pounder breech-loading guns, firing segment shells with E time and C percussion fuzes. Five rounds were fired from each gun, the elevations varying from 3deg. 31min. to 3 deg. 10min., and the length of the fuze from 2.23 to 1.95in. The time fuzes were set too long for the range, so most of the shells burst on graze of percussion fuze. In the front row of targets, four segments and splinters went

each gun with common shell and F time and C percussion fuzes. The elevation of the gun was from 3deg. 10min. to 3deg. 12min., the length of the fuze 2.0in. The bursts were two prematures, five in front, from 20 to 75 yards short of targets, and two through. The result was, on the front targets, nine through and one struck; and on the rear targets, ten through and four struck. 'The cause of the premature bursts was too deep a socket in the shell, a little play being allowed for the C percussion fuze, a defect which was afterwards remedied. The second half battery (A) of three 9-pounder breech-loading guns, firing Boxershrapnel shell, with 5sec. wood time fuzes, then took their turn. Fifteen rounds were fired at an elevation of 3deg. 12min. throughout; the fuze, for the first nine rounds, was bored at 0.7in., and for the remainder at 0.65in. The burst was seven in front, varying from 10 to 150 yards short of targets; eight grazed and blind. The effects were, on the front row, 54 bullets and splinters through, four lodged, and nine struck; on the rear row, 50 through, eight lodged, and 21 struck.

The third part of the experiments was carried out by the first half battery of the 12 pounder C battery, which fired Boxershrapnel shells and 5sec. wood time fuzes. Five rounds were fired from each of the three guns at 2deg. 50min. elevation throughout. The fuzes were bored at 0.6in. for the first and last three rounds, the intermediate being at 0.65in. With the 0.6 fuze the bursts all took place at points from 35 to 175 yards in front of the targets. The 0.65 fuze gave as a result one burst just in front of the targets; another, 120 yards to the front, the remainder being beyond the targets. The remainder being beyond the targets. The front row of targets had 69 bullets and splinters through, 10 lodged and nine struck, whilst the rear row had 68 through, 14 lodged, and eight struck. The second half of the same battery (C) then came into play, firing five rounds from each of their three guns, segment shells, with E time and C percussion fuzes, being used. The clevation was from 2deg. 55min. to 2deg. 50min., the fuzes were set to 1.95in., and gradually reduced to 1.7in., their proper length, for the last six rounds. In the first nine rounds, there were three bursts on graze at distances of from five to 40 yards in front of the and six on graze to the rear. The last six rounds all burst by time fuze from 30 to 175 yards in front. The front targets had 24 segments and splinters through, 26 lodged, and 42 struck. In the rear row, nine went through, four lodged, and 14 struck. This concluded the proceedings for the day, which are to be resumed, and we shall place the results before our readers in due course.

#### THE ISTHMUS OF SUEZ COMPANY.

N the execution of any public or private 1 enterprise, the promoters have not only to supply the "sinews of war" and carry on the campaign during the progress of the works, but, in addition, they rarely receive any advantage until the works are completed, and the whole affair placed au courant. interest allowed on all paid-up calls can scarcely be said to come under the head of any distinct commercial advantage or benefit accruing to the shareholders. It is but therefore, that all companies should look a little beyond the mere present, and endeavour to secure for themselves such rights and privileges as may in the end com-pensate them for the risk they undergo, the perseverance they exhibit, and the energy they display. There are so many energetic and enterprising individuals and companies in our own country, that very little difficulty through; one lodged and three struck. On the rear row there were three through, and one large hole caused by a shell bursting close up. Three rounds were then fired from

out works of an industrial and engineering description are comparatively so great in a civilized and highly cultivated country, that the task is not of so serious or arduous a nature as in a land where a railway is unknown, and where an ordinary road is some-thing to be proud of. Hence it is that the inducements held out to capitalists and companies to start railways, roads, tramways, canals, harbours, and other works in comparatively uncivilized and unexplored countries, are of a very high order. They usually include immunity from competition, a grant of—what would be considered by us—an enormous amount of land in the immediate vicinity of the line of project, and the right of valuable productions that may happen to be situated on the land granted. When it is borne in mind that a railway or other extensive artery of national intercommunication is almost invariably the avant courier of pro-sperity, commercial industry, and growth of population, it is no wonder that many such undertakings are carried out more for the sake of the extraneous advantages attached to them, than for the benefit of the actual receipts derived from them when completed. This arrangement is also advantageous to the Government of the country, which always stipulates for the ultimate purchase of the works after the lapse of a certain time, should it desire to do so, as it is thereby enabled to assume the control over them, without at the same time entrenching upon the other rights it has accorded to those who promoted the

project.

Now that the piercing of the Suez Canal is almost a fait accompli, it is only to be expected that the company is somewhat anxious to secure to itself the prospect of an adequate and permanent reward for all that it has gone through. Previously to the recent departure from Egypt of the Viceroy, a new arrange-ment was entered into, which concludes satis-factorily the several items of negociation which had not been definitely settled during the earlier stages of the proceedings. is, the company receives a first indemnity of £1,200,000, and has been accorded permission to sell certain lands in conjunction with the Viceroy as part owner. On its side, the Company, after 1st October next, cedes the privilege it has hitherto enjoyed of importing, free of duty, all materials necessary for the canalization of the isthmus. After that date, not very far distant now, it will come under the ordinary regulations prevailing in the country on everything relating to the importation of foreign materials. An indemnity of £800,000 is allowed to the company as a "set off" against its abandonment of the monopoly of the fresh water canal, which had been formerly granted to it. For the future, its control will be limited altogether to the salt water or maritime canal which, from first to last, was the main object in view. construction of the smaller work was imperative upon the company, as an indispensable preliminary to commencing that gigantic task which has been narrowly and jealously watched during every stage of its progress by the whole of the civilized world. It is unquestionable that many of the lookers on were unwilling witnesses of the well-merited success that has attended the indefatigable exertions of M. Lesseps, and a few of them would probably have rejoiced had the whole project eventuated a failure, were it only to demonstrate the truth of their own ill-omened predictions. Until the small or fresh water canal was manifestly approaching completion, these erroneous prophecies were still persisted in; but the absolute junction of the two seas—the "meeting of the waters"—gave the death blow to the hopes of those who were -gave the

antagonistic to the enterprise.

mutual satisfaction. During its temporary occupation of the site, the company found themselves obliged to erect hospitals, magazines, stores, and buildings, many of which were of a permanent and durable character. Their extent and value may be estimated from the fact that the Viceroy pays the company £400,000 for their becoming his property. This cession includes the extensive magazines of Boulak and Damietta, all the hospitals and buildings attached to them, and the premises and workships established in connection with the quarries and harbour of Mex. It is also stipulated that there shall be an ulterior arrangement respecting the disposition of 25,000 acres at the disposal of the company, and situated along the banks of the maritime canal. The same clause provides for the land that was originally appropriated to the extension of Port Said and Ismailia. The object of all this negociation is evidently the desire on the part of the Egyptian Government to exercise the supreme control over the management of the canal, and thus reserve to itself the right of imposing and levying all dues regulating the export and import duties, and, in fact, opening or closing the canal at its own good pleasure. It is to be hoped that so great and arduous a work will remain ever devoted to the interests of peace, and that its sole mission will be to promote the com-mercial welfare and prosperity of the different nations which may send their vessels through its waters. At the same time, it would be idle to deny the possibility of a hostile gunboat endeavouring to force a passage; and for this reason we sincerely trust the efforts being at present made by the Viceroy to secure to the world at large that the Suez Canal shall be neutral water during war time may be successful. All that is required is the co-operation of the nations of Europe, and the affair is accomplished.

#### SCREW PROPULSION.\*

WE have now come to the last part of Mr. W Burgh's treatise on Modern Screw Propulsion—or, rather, the last part has come This completes a work which abounds in useful information upon a subject of the highest importance in connection with the practice of marine engineering in the present Those who have followed us in our occasional notices of this work will have observed that it contains articles on the various branches of the subject, which have been written by some of our leading marine engineers, who are thoroughly competent to deal with the matter. Thus, we have Mr. Penn supplying information upon lignum vitæ bearings, Messrs. Maudslay upon the practice of feathering screw propellers, and Mr. G. B. Rennie upon screw propulsion generally. Then Mr. Griffiths has explained the principles upon which his screw propeller is founded; Mr. C. Barclay has discussed the geometry of the feathering paddle wheel, and Mr. Langdon has given the proportions for thrust blocks. In another direction, we have Captain T. E. Symonds, R.N., and Messrs. Dudgeon, informing us upon the principles and practice of twin screw propulsion; whilst Mr. Arthur Rigg has detailed his experience with regard to the use of vanes in connection with the screw. Mr. Burgh himself has contributed various articles on the general subject, as well as others on detail principles, so that the result is a collection of valuable facts and figures, which we can well recommend to all who seek reliable information upon the whole subject of screw propulsion. But in taking leave of Mr. Burgh, and while complimenting him upon the value of the information contained in his work, we should be unjust to him and to the public if we failed to record that a large

\* "Modern Screw Propulsion." By N. P. Burgh, Engineer. London: E, and F, N. Spon, 48, Charing Cross.

amount of that information is conveyed in language so obscure, so involved, and frequently so ungrammatical, that its value is greatly reduced. The reader is often obliged to guess what the writer's meaning really is, whilst there are passages which are of very doubtful purpose altogether. These remarks apply to those chapters which have been written by Mr. Burgh himself, and which form a contrast to the plain clear statements of the other contributors. It was once Mr. Burgh's great delight to indulge copiously in Latin phrases, and quotations, and italics about every fifth line or so, bearing evidence of the free use of either the one or the other, or of both. remonstrances on these heads appear to have prevailed with Mr. Burgh, in one respect; he has long discontinued the use of his Latin, but he still adheres to his italics. Now, nothing looks worse in a book, and nothing is more interrupting to a reader, than a constant recurrence of words and phrases in a type different from that of the general body, If Mr. Burgh thinks to strengthen his propositions by thus frequently emphasising his expressions, he is mistaken. His arguments frequently become weakened by the indiscriminate and injudicious use he makes of italics, which are often applied in the most unmeaning manner. They are to the reader like the constant thud of a stump orator's fist on the table. So that here we have two causes operating to detract from the value of a work which otherwise undoubtedly possesses great merit. We trust Mr. Burgh will endeavour in his future productions—for we do not suppose he has done with the pen yet— to avoid these two evils; and by a clearer diction, and a renunciation of italics, will make his writings as perspicacious as are those of his fellow labourers in the field of scientific literature.

#### ELECTRICITY AND TELEGRAPHY.

THE "Hull" steamship, having on board the Black Sea cables, for the Indo-European Telegraph Company, has arrived safely at Gibraltar. The principal cable may be expected to be laid at the end of the month.

The repairs to the "Calcutta" have been completed, and she is now having the Persian Gulf cable, that was taken out of her at Plymouth to allow the ship to be docked, coiled on board again. She may be expected to leave Plymouth in about a fortnight; and the "Tweed," with the other portion of the cable, will leave the Victoria Docks about the same time. The delay unavoidably caused by the accident to the "Calcutta," has this advantage—that the submergence of the cable will take place now in a cooler season of the year than it would have been had the cable expedition left at their appointed time. The operations in connection with the "Calcutta" section of cable have been somewhat difficult and excessively tedious. All the cable that remained in the ship had to be coiled on shore in temporary "coils," erected specially. The seventy miles of cable payed out from her, to lighten the ship after the collision, had to be recovered. The operations in connection with this were carried out under the personal superintend-ence of Mr. F. C. Webb, C.E., and the difficulties attending upon recoiling the seventy miles on board in a proper state may be imagined when it is borne in mind that that length was payed over the ship's side without assistance of machinery,

and when she was drifting at various speeds.

The "Porcupine," surveying ship, has left Woolwich on a dredging and scientific expedition for the West Coast of Iceland, and the investigation will comprise the sounding of the North Atlantic bed, between Cape Clear and the Farce Isles. A novelty in sounding will be introduced in the expedition—the observation of the temperature of the bottom, by means of electricity. This will be done with the aid of Mr. C. W. Siemens' electric resistance thermometer, to which we lately called atten-

pleted at the cable works of Mr. W. T. Henley, is now being shipped on board his ship "La Plats and as the whole of the cable—285 miles—will be soon on board, the ship may be expected to leave in about ten days or a fortnight. The cable is an iron covered cable, containing only one wire, insu-lated with Hooper's material.

The United Kingdom Telegraph Company have

opened their new route to Russia, and it is shortly expected that an additional route will be opened by submarine cable to Russia via Sweden; the present route consists principally of submarine cables, from Newcastle to Denmark, and from Denmark through the Baltic to Liban in Russia.

The new British Indian cable has not yet commenced to be sheathed, but a commencement will be made immediately—probably at the beginning of next week. The directors, however, announce the obtaining of several valuable concessions for extensions to China. The new scheme is to conextensions to China. The new science is to connect the British Indian, by a line of telegraph,
from Bangkok through Siam and Cambodia
to Saigon, and thence to Cape St. James
or Cape Podaran, from which place a submarine
cable will be laid to Hong Kong. The privileges
obtained include exclusive rights from the French authorities at Saigon for forty years, the concession from Siam for ninety years, and the exclusive right of communication through Cambodia. We may, therefore, expect that on the successful com-pletion of the British Indian scheme, active and energetic measures will be undertaken for the furtherance of direct telegraphic communication with

The Anglo-American Telegraph Company have just had their ordinary general meeting, and a dividend was declared, making the total dividend of the year a little over 24 per cent., after placing to the reserve fund the usual amount. The repairs to the 1866 cable, which was interrupted in the course of the year, cost £10,000, and the amount course of the year, cost £10,000, and the amount was not considered excessive, when it was borne in mind that a vessel, with skilled hands, had to be sent over to carry out the repairs. Although it was stated that a ship would be specially maintained at Newfoundland to undertake whatever repairs might be required, nothing yet seems to be done; but it would seem advisable, if every repair is to cost that enormous sum, that some steps, as to efficient maintenance, should be taken. It is thought by the most qualified judges of such It is thought by the most qualified judges of such things the safest and most economical plan, and now more than ever desirable when the cables on that coast are on the increase. The almost immediate submergence of the French Atlantic cable was looked upon favourably, as tending to the increase of business, a result that could only be productive of good to them.

The movements of the French Atlantic cable expedition are most satisfactory; the "William Cory" is on her way to St. Pierre, and the "Chiltern" has left for Brest to lay the shore end. The "Great Eastern" left Sheerness on the 12th, and anchored below the Nore the same day. On the following morning she left for Portland, where she arrived on the afternoon of the 14th. The followarrived of the atternoon of the 14th. The holder ing morning she began taking in coals, and it is anticipated that, accompanied by the "Scanderia," she will leave for Brest on the 20th. A grand féte and great rejoicings are to take place at Brest, on her arrival off there, to celebrate the event of laying a submarine cable from France. From our latest accounts, the electrical tests show that the cable is in a very perfect state.

There is every hope that in a few days the money bill for acquiring the electric telegraphs will be brought into the House of Commons. The various arbitrations have come to an end, and the remaining agreements settled. The greatest delay has been due to the arbitration with Reuter's Telegram Company, a large mass of evidence having to be gone through. The whole of this, however, has been completed, and the umpire has given his award, which amounts to the sum of £726,000, each party having to pay their own costs. This amount is somewhat in excess of that which the Post Office had offered to give. The arbitration with several other companies depended greatly upon the Reuter arbitration; and the announcement has been made of the satisfactory settlement of the claim of the Electric and International Telegraph Company, by far the largest claim of all. The actual sum to be paid for their undertaking is £2,938,000, a deduction of £400,000 having been made for depreciation of plant, repairs, and renewal on.

The Peterhead and Norwegian cable, lately companies have increased greatly in value. It is strongly to be hoped that

the measure will at once be brought forward and passed, for the present state of uncertainty is greatly against telegraphic extension in the United King-

ON RECENT DISCOVERIES IN NOTES SCIENCE AND THEIR PRACTICAL AP-PLICATIONS.

SELF-INFLAMMABLE MIXTURES-EASY PROCESSES FOR THE DETECTION OF SULPHUR AND PHOSPHORUS NEW THERMO-ELECTRIC PILE-WHAT IS THE NA-TURE OF GRAHAM'S COMPOUND OF HYDROGEN AND PALLADIUM?

T may be thought that we have a sufficient number of destructive agents at hand already, and that the worst practical applications of science are made when they are added to. We are somewhat of the same opinion, but our duty to our readers, and to the public in general, obliges us, when we meet with matters of this kind, to give an account of them, satisfied that, after all, publicity is the greatest safeguard against their employment. M. Nickles has just published a paper on Greek fire, in which, of course, Fenian fire comes in for a long notice; and he also describes a novelty to us which, it seems, is known in France as the feu lorrain. This latter compound is certainly far more dangerous than the solution of phosphorus in bisulphide of carbon, which obtained the name of Fenian fire; but, at the same time, it is more difficult to employ, since the ignition is instantaneous and violent. The ingredients of the composition are a solution of phosphorus in bisulphide of carbon and chloride of sulphur. When strong liquor ammonia is added to this mixture, violent chemical action ensues, and sufficient heat is developed to instantly ignite the inflammable ingredients. easy to see how such a mixture could be applied to incendiary purposes. A thin glass bottle containing the ammonia could be placed in a larger containing the inflammable mixture, and then, if this were thrown against any object, sufficient violence to break the ammonia bottle, an explosion and a fire must necessarily ensue An experiment may be made by placing some of the mixture in a porcelain dish, and pouring some ammonia upon it; but the experimenter is recom-mended to fix his ammonia bottle on the end of a long stick, and put a safe distance between himself and his experiment. For the lecture-room, an illustration may be given by introducing a strip of filtering paper soaked in strong ammonia into the mixture by which it is ignited, but the action is not so sudder M. Nickles concludes his paper by nor so violent. showing how this mixture and the Fenian fire should be treated to render them harmless. The simplest means is obviously to add to them a solution of oxide of lead in an alkali, by which the phosphorus and sulphur will be converted into harmless and

uninflammable compounds. Writing of sulphur and phosphorus reminds us of some very simple methods of detecting these substances, both in organic and inorganic com-pounds. If we have, for example, an insoluble powder, supposed to be sulphate of barium, it is only necessary to take a grain or two, place it in a thin test tube, throw in a small fragment of potassium or sodium, shake the tube so as to surround the metal with the powder, and then apply heat. In this case, as, of course, with any other sulphates, reduction quickly takes place, and a layer of red sulphide of potassium will be seen on the sides of the tube. Then, if water and acid be added after the tube has cooled, sulphuretted hydro gen will be evolved; or, if water alone be added. the sulphur will be recognized by the beautiful violet colour produced on the addition of nitroprusside of sodium. Metallic sulphides may be similarly treated, but the author cautions us that in the use of realgar the action is violent, and attended with explosion. Dry organic matters, such as hair, nail, or feathers may be treated in just the same way to show the presence of sulphur; but liquids, such as albumen and saliva, or moist skin, require to be dried and carbonized before the potassium or sodium is added. We may mention here that the process is well adapted for the detection of wool with silk. A few fine cuttings of the material should be introduced into a tube with a fragment of one of the alkaline metals, and heated, as described; and then, if wool be present, the aqueous solution will give the re-action of sulphur with the nitro-prusside. Phos-

phorus is found in a very similar way, magnesium peing employed in place of one of the alkaline metals. The powder experimented with must be perfectly dry, and an excess of fine magnesium filings must be used. The application of a stronger heat is also necessary. In this case, a phosphide of magnesium is formed, and when water is added to the cooled mixture, phosphuretted hydrogen is evolved which is recognized by its peculiar onion-like odour, or, if sufficient phosphorus was present, by the spontaneous inflammability of the gas. A grain or two of brain-matter completely carbonized and heated with magnesium will give distinct evidences of phosphorus. These simple processes, which, we ought to state, have been devised by Dr. Schonn, of Stettin, will be found of great use to chemists from their simplicity, and the rapidity with which the experiments may be made.

A new thermo-electric pile is described by MM. Mure and Clamond, in which galena forms the negative element and iron the positive. galena is cut into bars 40 millimetres long and 8 millimetres thick, and thin sheet iron plates 55 millimetres long and 8 millimetres wide, are con-The inventors arrange a series of these so as to form a hollow cylinder, in which a gas burner is placed. The insulations, we should have said, are made with thin plates of mica. Although with forty of these couples the intensity of one Bunsen's cell is obtained, it is hardly necessary to say that we are a long way from getting the electric equivalent of the heat employed.

Mr. Graham's discovery of the occlusion of gases by metals has attracted much attention in France. and several chemists and physicians have repeated the experiments, and expressed their views on the nature of the union which takes place. jority appear to agree with Mr. Graham in regarding hydrogen as a metal, and consider the combination of hydrogen and palladium as an alloy. Favre, however, has come to another conclusion. He expresses an opinion that a more intimate chemical union takes place, and that a hydride of palladium is formed. This view of the nature of This view of the nature of the compound can hardly have been overlooked by so acute a chemist as Mr. Graham, and that he did not adopt it is conclusive, to our mind, that it is not supported by the facts of the case.

#### PARLIAMENTARY NOTES.

YESTERDAY week, while we were going to press, the question of fortifications, shields, and the Moncrieff gun carriage was mooted in the House of Commons. In opening, Captain F. Beaumont called attention to the expenditure to be incurred in completing our fortifications, so far as it related to the protection of guns by means of shields or the use of the Moncrieff gun carriage, The hon, and gallant member said that 20 years had elapsed since we were called upon to look for something to offer resistance to the increasing power of modern ordnance; he mentioned the appointment of the Iron Plate Committee, which sat from 1861 to 1864; of the special committee, better known as the Gibraltar Shield Committee, which reported in 1868, and of the Select Committee, a committee of scientific officers and others, sitting en permanence, who gave place in 1866 to the Committee on Inventions, now sitting; and he enumerated the experiments made by the Iron Plate Committee. The failure of the Gibraltar shield, constructed on the principle of bolting thicknesses of iron together, led to the appointment of the second committee. In February last, an important experiment was made at Shoebury-Three 5-inch plates sent to be tested were bolted together, 6in. apart, and the spaces between them were filled with asphalte. The shield thus made measured 27in. in thickness, and it was fired at with extremely satisfactory results. Further experiments had confirmed the good opinion formed of this shield, which, in all probability, would form a pattern for the future armour for fortifications. But, although the shields had been satisfactorily proved, the means of defending our guns had been imperfectly tested. The Moncrieff gun carriage, which in form represented a rockinghorse with the gun placed on the tail and a weight botween the fore legs, acted so as to cause the gun to be raised by the recoil of the discharge and a anical contrivance kept the gun under cover until it was lowered to be fired again. The defensive power of this invention had been proved inquiry, he would move that an humble address be

but not its offensive, and he feared the invention had been purchased too hurriedly, for if it realized all that was promised the inventor had been ill paid, and if it fell short of what was promised it had been dearly brought. The Moncrieff system should be tested under circumstances similar to those of war. Let Captain Moncrieff make a gun according to his own views, and the War Office a shield of the most approved construction, and let the two be tried against each other. Besides this. he urged the importance of setting the ingenuity of the country at work by inviting competition in shields, because he did not believe the construction of our fortifications could be proceeded with consistently with prudence on the basis of our present knowledge of the science of armour.

Mr. Cardwell was much obliged to his hon. and gallant friend for having postponed bringing forward this question upon a previous occasion, but hoped he would not expect him to go at length into the subject at midnight, especially as opinion upon scientific subjects would not be highly valued by the House. Still, he must observe that gun carriages and shields were not things which could be contrasted with each other in the way the hon. and gallant member proposed. Mr. Moncrieff's most skilful scheme had been brought before him first by the Ordnance Committee, which had considered it most carefully. It had received the entire approval of the authorities at the Horse Guards, and within the last few days he had laid upon the table the report of the committee appointed by his right hon. friend opposite likewise speaking in the highest terms of the invention. Under these circumstances, it was unnecessary for him to enter further into the subject. He had not the least doubt that the shields would soon be in their places. And when the House voted, as he felt persuaded they would do, the sum awarded to Mr. Moncrieff by Lord Northbrook's Committee, they would have made, he believed, a most satisfactory arrangement.

Sir J. Hay, as chairman of the Iron Plate Committee and of the Gibraltar Shield Committee, confirmed the statement of the Secretary of State for War, that it was impossible to contrast the two subjects of iron shields and the Moncrieff gun, both of which were extremely valuable inventions, and both of which when properly placed would become highly serviceable additions to the defences of the country. The Moncrieff gun had been referred to as a kind of hobbyhorse, and he hoped the hon. member opposite would not attempt to ride that hobbyhorse to death. It would be very useful in its proper place, and he hoped his right hon, friend opposite, and everybody who might follow him in the office of Secretary of State for War, would see that the invention was only applied

to its proper purpose. Last Tuesday ovening, the probable exhaustion of our coal fields, as predicted by Sir W. Armstrong, troubled the House for a while. Mr. Poase opened the question by calling attention to the need of an report from the Royal Commission appointed in 1867 to inquire into the duration of the coal fields. The hon, gentleman said his object was rather to elicit information than to communicate it. At various times the question of the exhaus-tion of our coal fields was brought before the country and that House. Without wishing to go very far back, he might mention the names of Dr. Buckland, Sir W. Armstrong, Mr. Hull, and Professor Jevons, each of whom had called attention to this important subject. Professor Jevons cal-culated the quantity of coal still available at 100,000,000,000 tons, and that if we continued the use of it at our present ratio we should exhaust it in 100 years. In 1866, the present Prime Minister laid great stress upon the enormous value of the national wealth in coal. In 1854 the consumption of the year amounted to 64,000,000 tons. In 1861 it was 81,000,000 tons, and at the present time it was no less than 84,000,000 tons. The honmember for Glamorganshire (Mr. H. Vivian) in June, 1866, introduced the subject to the House in an able and interesting speech. The result of that speech was the appointment of a Royal Commission, consisting of the Duke of Argyll, Sir R. Murchison, Sir W. Armstrong, the hon. members for North Durham and Glamorganshire, Mr. Forster, himself (Mr. Pease) and several other gentlemen. That commission proceeded to investigate the probable quantity of coal contained in the coal fields of the United Kingdom, and the probable consumption of the same. Several subsidiary questions were proposed to this commission, which required a considerable amount of organization, time, ability, and labour to investigate. As that commission had now concluded their presented to Her Majesty, praying that she would be graciously pleased to take such further steps as she may be advised, in order to procure from the Royal Commission on the exhaustion of our coal fields, appointed in July, 1866, a report early a date as the difficult character of their investigation will permit.

In seconding the motion, Mr. H. Vivian described the progress made by the commissioners in their inquiries. He stated that the commission commenced their sittings on July 7, 1866, and, as several points of the utmost difficulty were subjected to the state of the mitted to it, it was considered advisable to delegate to several committees of this commission the investigation of the leading points into which the subject naturally divided itself. The first committee had submitted to it the question as to the possible depths to which our coal mines could be worked. The second committee undertook to inquire into the question whether waste occurred in the consumption of our coal. The third question referred to a committee was whether waste occurred in the working of our coals. The fourth question was whether coal existed under a super-incumbent strata. The fifth was the probable future consumption of coal in this country. Each of these questions had been fully investigated, and all the reports were nearly completed. Sir R. Murchison reported as to the extent of our coal fields that the results of the inquiry were most satisfactory, inasmuch as there was every reason to believe that there was a large amount of good fuel procurable for a very long period, even after the exhaustion of our known coal fields. result of the investigations into the Gloucestershire and Somersetshire coal fields was that not more than one-fortieth of the supply had been exhausted, and he hoped and believed that our other coal fields would prove as valuable. The commission was doing useful work at an annual expense less than a thousandth part of what was every year spent on the army, and it was important that the report should contain, not only the information collected, but well-founded conclusions based on it. He, therefore, protested against undue haste being urged upon the commission. however, highly satisfactory to know that enough had been already ascertained to prove that our coal supply was sufficient to last for many genera-

Mr. Secretary Bruce said that, as the commissioners had been prosecuting their work for three years, it was only natural that a desire should arise on the part of the House and of the public to learn the point at which they had arrived; and the feeling of curiosity which existed upon the subject had fortunately been gratified by the instructive address of the hon, member for Glamorganshire (Mr. H. Vivian). The explanations which the hon gentleman had given showed the vast extent of the inquiries which the commissioners had to institute, and it was impossible that these inquiries, if properly conducted, should not extend over a considerable period of time. He was sure, however, that the labours of the commissioners, when their report was published, would be found to have been worthily bestowed, and that they would throw the most valuable light on a question in which this country was most deeply interested. In the meantime, it was satisfactory to find that there were good grounds for believing that our supply of coals was practically illimitable. But it was, no doubt, also desirable that we should, as far as possible, economize those fields which were more easily accessible, and that we should thus be enabled to meet upon the most favourable terms the competition of foreign manufacturers. He had only to add that he hoped the hon. member for South Durham would not think it necessary, after what had passed in the course of the discussion, to press his resolu-tion upon the House.

The hon, member for South Durham did not appear to think it necessary to press his resolution, which was accordingly withdrawn. It is to be hoped that the commissioners will be allowed ample time to digest the information they have obtained. It is of the greatest importance for the satisfaction of the country and the alleviation of certain unfounded apprehensions, that the real state of the case should be accurately ascertained and deliberately made known.

FROM Peru it is stated that the loading of the guano at the Guanape Islands is going on, and that the commissioners lately sent thither to report upon its quality and other points have returned with the announcement that the greater part of the deposits will compare favourably with those from the Chincha

#### RECENT LAUNCHES.

AST Saturday witnessed the successful launch of a new ironclad for the Turkish Government, from the yard of Messrs. Samuda Brothers, at Poplar. She is called the "Moyini-Zaffer," which means "The aid to victory." Her length is 230ft.; breadth, 35ft.; depth, 27ft. Her burden is 1,400 tons, and her displacement 2,400. Her armament will be four 12-ton rifled guns, placed in a double central battery, so arranged that they can be all fired on one broadside, or can be trained to fire in a line nearly parallel with the ship's course as bow and stern chasers. She was designed by Mr. Mackrow, of the Thames Iron Ship Building Company, and is sister ship to the vessel built by that company for the Turkish Government, and launched two months since. She is intended to run at a very high rate of speed, and if the expectations of her designer and builders be realized, she will be the fastest vessel of her class afloat.

Messra. Day and Co., of the Northam Yard, Southampton, have just built a fine steamship for the Peninsular and Oriental Steam Navigation Company, and which was launched from their yard also on Saturday last. The "Hindostan"—as the vessel is named—is the largest ship ever built in the port of Southampton, and will be the largest of the Peninsular and Oriental Company's steam Her leading dimensions are as follows:-Length between perpendiculars, 349ft. 10in.; length on loadwater line, 344ft. 4in.; length over all, 382ft. 8in.; breadth, moulded, 42ft. 3½in.; depth, 33ft.; tonnage, builders' measurement, 3,086 tons; and she will be fitted with engines of 600-horse power. Below the water-line she is built with the best Staffordshire iron, and steel above. She is fitted with a topgallant forecastle and cut-water, figurehead, iron bowsprit, and elliptical will be bark rigged, with the three lower masts and fore and main yards of iron. Accommodation is to be provided on board for 176 first and 55 second class passengers, and she will have capacity to store 800 tons of coals in her bunkers, and 1,400 tons of cargo in the holds. On the adjoining stocks to those lately occupied by the "Hindostan," another fine iron steamship is fast "Hindostan," another fine iron steamship is fast approaching completion for the Royal Mail Company, to be called the "Nile." This vessel is about 2,700 tons, builders' measurement, length between perpendiculars, 347ft.; breadth of beam, 40ft.; and depth, 33ft. She will carry 8/00 tons of cargo and 1,250 tons of coals, and will have a large amount of accommodation for passengers. The engines for the "Nile," which are of 600-horse power, are also under construction by the same firm. Both also under construction by the same firm. Both the "Hindostan" and the "Nile" have been built from designs by Mr. John Macormac, the naval architect of the "Surat," the "Allemannia," and other steamships, constructed at the Northam Iron Works.

#### EXAMINATIONS IN SCIENCE BY THE SCIENCE AND ART DEPARTMENT.

THE Annual Science Examinations of the Science and Art Department were brought to a close on Saturday, May 29. This was the ninth general examination that has been held since the establishment of the system of aid to instruction in science in 1859. The examinations are superintended by local committees. They were in this way held at 437 centres this year, whilst last year they were only held at 261. At that time there were about 15,000 students under instruction; this year there were 25,000, and the number of papers worked shows a similar increase having risen from 13,112 to 23,997. The number The number of candidates in the various subjects was as follows :-

In geometrical drawing there were 2,547, last In geometrical drawing there were 2,047, last year there were 1,337; in machine drawing 2,997, last year 1,671; in building, construction, and naval architecture 1,993, last year 1,206; in elementary mathematics 2,302, last year 1,390; in higher mathematics 85, last year 33; in theoretical mochanics 631, last year 353; in applied mechanics 284, last year 167; in acoustics, light and head 1,250 lest year 167; in acoustics, applied mechanics 284, last year 167; in acoustics, light, and heat 1,350, last year 769; in magnetism and electricity 2,480, last year 1,038; in inorganic chemistry 2,166, last year 964; in organic chemistry 210, last year 123; in geology 609, last year 309; in mineralogy 67, last year 38; in animal physiology 2,227, last year 1,182; in zoology 303, last year 298; in vegetable anatomy and physiology 144, last year 112; in systematic and economic botany 90, last year 73; in mining 48, last year 41; in metallurgy 120, last year 81; in navigation 303, last year 219; in navigation 303, last year 219; in navigation 303, last year 86; in steam deaths by railways, manner not stated, 465.

148, last year 106; and in physical geography

2,786, last year 1,516.

This is the first examination at which the scholarships of £100 per annum, founded by Mr. Whitworth, have been competed for. There have been about 120 candidates for them, and as soon as the results of all the theoretical examinations have been made known, the practical examination will be proceeded with in the manner detailed in the minute of the Lords of the Committee of Council on Education.

#### THE BRITISH ASSOCIATION.

MEETING of the Council of the British Association was held last Saturday, Sir Roderick Murchison in the chair. It was reported by the general secretary that the following presidents of sections had consented to preside at Exeter meeting, and the following vice-presidents were nominated:—Section A (Mathematical and Physical Science).—President, Professor Sylvester, F.R.S.; vice-presidents, Professor Adams, F.R.S., and Mr. W. R. Grove, Q.C., F.R.S. Section B (Chemical Science).—President, Dr. Debus, F.R.S.; vice-presidents, Professor Odling, F.R.S., and Professor Williamson, F.R.S. Section C (Geology).— President, Professor Harkness, F.R.S.; vice-presidents, Mr. R. Godwin-Austen, F.R.S., and Mr. W. Pengelly, F.R.S. Section D (Biology).—President, Professor Rolleston, F.R.S.; vice-presidents, Mr. C. Spence Bate and Mr. E. B. Tylor. Section E (Geography).—President, Sir Bartle Frere; vice-presidents, Sir George Grey, K.C.B., and Mr. A. G. Findlay, F.R.G.S. Section F (Economic Science and Statistics).—President, the Right Hon. Sir Stafford H. Northcote, M.P.; vice-presidents, Mr. T. D. Acland, M.P., and Colonel Sykes, M.P., F.R.S. Section G (Mechanical Science).—President, Mr. C. W. Siemens, F.R.S.; vice-presidents, Mr. G. P. Bidder, F.R.G.S., and Mr. C. Vignoles, F.R.S. The Mayor of Exeter, Sir Stafford Northcote, and Sir John Bowring were present, and supported the application of the working men for a special lecture during the meeting, which was unanimously agreed to, and, subsequently, Professor W. A. Miller, vice-president and treasurer of the Royal Society, was invited to undertake the duty. This learned professor of chemistry, King's College, London, is well known as an excellent lecturer to large audiences, and is highly distinguished for his recent researches in the chemistry of the sun conjointly with Mr. Huggins, F.R.S. The proposal of the Chamber of Agriculture to hold a meeting jointly with the British Association was referred by the Council to Sir Stafford Northcote, as president of the section in which agricultural subjects are usually discussed.

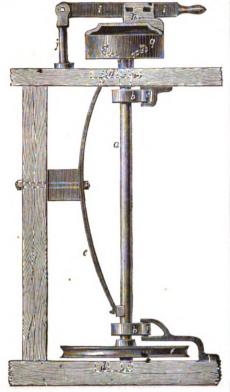

#### CENTENARY OF THE STEAM ENGINE.

I SUPPOSE the engineers of Britain are not forgetting that this is the centenary of the birth of Watt's condensing steam engine. Before 1769 his model room; but in April of that year a patent was granted tor it, and the world first knew of the tender child which brought poverty to its rearers, but which has grown to a wealthy giant in these latter times, and coined and scattered millions over the world. If Watt and his masterpiece deserve the honours that have been poured upon them, then have they a right to some sort of commemorative recognition during this, the hundredth year of the engine's life, and one naturally looks to the profession to take the initiative. We are glad of an excuse for crowning the bust of a poet, or for celebrating the birth of a musi-cian; let us not be backward in honouring the memory cian; let us not be backward in honouring the memory and the works of him who, as Brougham modestly inscribed on Chantrey's statue, enlarged the resources of his country, increased the power of man, and rose to an eminent place among the real benefactors of the world. This year, too, is the fiftieth since the death of Watt. It is also the centenary of the birth of his son, James Watt, the younger, and of many a great man besides. Humboldt, Cuvier, the first Brunel, Wellington, Marshals Soult and Ney, and Sir Thomas Lawrence were all born in 1769. Ark-wright's spinning-ienny patent bears the same date. wright's spinning-jenny patent bears the same date.
Truly, as a commemorative year, 1869 is remarkable.
—"Once-a-Week."

#### MACHINE FOR MANUFACTURING POTTERY.

MR. WILLIAM BOULTON, of Providence Foundry, Burslem, has patented the apparatus shown in the annexed cut, the object of which is to give an eccentric or irregular motion to articles of pottery made by the "jigger" or "whirler." Two oval or irregular cams are fixed on the jigger spindle, and are brought in contact with the friction pulley by a spring, the carrier of the pulley being stationary; the neck and toe blocks of the jigger spindle being made to slide, give a motion to the spindle according to the shape

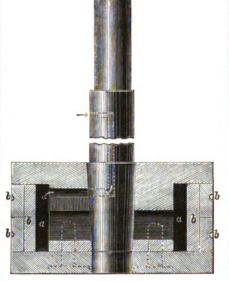

of the pulley. In our cut, which shows a side elevation of the machine, aa is an upright spindle, b b the pulleys or cams on the spindles, c c the friction pulleys, d d the footstep and neck block. e e the spring to keep the two pulleys in point of contact, f f the driving pulley, which is made either flat or grooved, and is to be driven by an endless driving belt; g g is the jigger head on which the dish or other article is made, h the profile to form the same, and i the lever lifting from joint j on which the profile is fixed.

#### PISTON PACKING.

MR. G. E. DONISTHORPE, of Leeds, has patented an improved method of packing pistons. In order to form a steam or fluid-tight packing to a piston or gland, he places around the piston or inside the gland a flexible bag of a ring form. This bag is distended by putting it in connection with a small reservoir containing a fluid which is maintained at a pressure exceeding the working differential pressure of the steam or other fluid with which the engine is worked by means of a piston or plunger forced inwards into it by a weighted lever or by a spring. The action of the lever is so regulated as at all times to be a the lever is so regulated as at all times to be a little above the working pressure in the cylinder at all parts of the stroke, especially when great expansion is adopted. In place of employing a bag, a groove may be formed around the piston or the gland, and this groove may be kept filled with fluid under a pressure greater than the working pressure in the cylinder of the engine. The parts may either be made to fit together sufficiently true to prevent too free an escape of the packing true to prevent too free an escape of the packing or lubricating fluid, or washers or leathers may be placed on either side of the groove to limit the cape of the packing and lubricating fluid. At escape of the packing and lubricating fluid. At the front of the groove around the piston or gland split rings of metal may be placed, so that the rings shall be pressed outwards from the groove by the fluid. These rings will also prevent too free an escape of the fluid from the groove around the piston or gland. The outer diameter of the gland would have to expand, and at the same time

the internal portion would have to contract, to effect a steamtight packing on the piston rod.

When Mr. Donisthorpe employs a bag packing, the bag is formed from two strips of leather, the two ends of each of which are first sewn together to form the strips of leather into rings one larger than the other, and the two rings are then sewn together edge to edge to form an annular bag. Each of the strips of leather from which the bag is made has projecting from one of its sides a short narrow strip, and these short strips are sewn together to form a tube leading into the annular bag. If the bag packing is for a piston, the bag is placed in a groove which is formed around the piston, and in the short tube projecting from the bag is inserted a small brass or copper tube which is passed through or connected with a passage formed through the piston and through the piston rod, and to the end of this pipe or passage is connected a small flexible pipe through which the fluid from a small reservoir under pressure is led into the bag packing. Or the bag packing may be put in connection with a reservoir of fluid under pressure. By this means not only will a sound packing be obtained, but a small quantity of the fluid going through the pores of the leather bag will afford the required amount of lubrication, or the end of the passage through the piston rod may be otherwise put in connection with the small reservoir in which the fluid for expanding the

packing and for lubricating is kept under pressure. The fluid in the reservoir is kept under pressure.

If the lubricating fluid under pressure be alone employed for effecting the packing, Mr. Donisthorpe (for packing a piston) forms the piston to fit very accurately to the cylinder as is now commonly done in the Allen engine, and around the piston are grooves of about in broad, and from the groove a passage is led through the piston and through the piston rod, and through this passage the packthe piston rod, and through this passage the packing fluid under a pressure greater than the working pressure in the cylinder of the engine is led into the grooves around the piston. By reason of the piston fitting very accurately to the cylinder, the too free escape of the fluid from the grooves will be prevented. This arrangement is very applicable in cases where water is employed as the lubricating fluid. As previously observed, washers of leather may be employed on either side of the groove to prevent too free an escape of the lubricating and packing fluid, and split rings of metal may be placed into the groove around the piston. Or it might be a gland, such an arrange-ment being shown in the accompanying cut. The piston is formed in a very similar manner to those in ordinary use, except that the groove a, in which the split rings b b are contained, is by a small passage c through the piston rod put in connection with a small reservoir, in which a lubricating liquid is kept under a pressure greater than the working pressure in the cylinder of the engine.

#### BOILER FLUE CLEANERS.

GOOD and efficient tool for cleaning the flues of A boilers has been the subject of much study on the part of mechanical engineers. The one illus-trated herewith, which we take from the "Scientific American," seems to have many points of excellence, which will become apparent to practical men upon

a description of its structure and operation. The letter A in the engraving indicates a portion of the handle which passes through a ring B, forged with and forming a part of the bar C. The handle A after passing through the ring B, screws firmly into the button D, which is also forged with the bar C and forms a part of it. The point of the bar C ha

a gentle curve toward the longitudinal axis of the a gentle curve toward the longitudinal axis of the handle A, and the other parts of the instrument, and is also tapered and rounded at the point. To the outside of the bar C is riveted the scraper plate E. This scraper plate, when uncoiled, is of rectangular outside of the bar C is riveted the scraper plate E. This scraper plate, when uncoiled, is of rectangular form, having an opening in the centre of the plate, of such shape as would be described by the intersection of two equal circles, the object of which is to multiply the cutting edges of the plate. The plate is bent spirally, so that two points are in line with the bar C, and the rivets which fasten the scraping plate to the bar and the other two points are brought round opposite the bar, as shown in the engraving. The handle may be made of gaspipe, which gives sufficient strength with less weight. The use of the button D is two-fold, i.e., to form an attachment for the handle A, and also to gather the soot and aid in its removal. The scraper plate bent in the form, and attached in the manner described, has great elasticity, and is therefore capable of being inserted readily into flues of different sizes and cleaning them equally well. The curved point of the bar C, in connection with the inclined edges of the scraping plate, compel the contraction of the latter, in entering flues of small size, while the elasticity of the plate forces its cutting edges firmly against the surface of the flues in the process of cleaning. We understand these scrapers have made a very favourable impression where they have been tried. This improvement was patented by Messrs. M. and C. H. Morse, of Franklin, Mass. C. H. Morse, of Franklin, Mass.

#### THE SOCIETY OF ENGINEERS.

WE are informed that the Council of the Society
Of Engineers have decided that the next visit
of their body shall be to the Chatham Dockyard
Extension Works. The Lords Commissioners of the
Admiralty have given their permission, and the
proposition is to make the visit on Friday, July 2,
next. Although the Society visited these works
last year, their importance and the progress made will
doubtless ensure a full attendance upon the occasion.
Moreover, it is proposed to charter a steamboat for
the conveyance of the members from London Bridge
to Chatham, so that the pleasure of the trip will thus the conveyance of the members from London Bridge to Chatham, so that the pleasure of the trip will thus be heightened. In order to allow the Council sufficient time for making the necessary arrangements for the comfort of the members, they should intimate their intention to be present on the occasion to the secretary, Mr. G. W. Harris, at the offices of the Society, 6, Westminster Chambers, Victoria-street. As members and associates may introduce their friends, we may expect the visit to Chatham to be the trip of the season.

#### THE MAURITIUS RAILWAYS-MIDLAND LINE.

By Mr. JAMES R. MOSSE.

BEFORE proceeding to the special object of this communication, which was to give an account of the working of some unusually heavy gradients, the chief physical features of the island, and the causes that led to the introduction of railways in the colony, were briefly noticed. The necessity for railway communication being M. Inst. C.E., was in May, 1858, charged by the Secretary of State for the Colonies to investigate the subject, and having reported in favour of the railway system, the construction of the works was authorized by the Imperial Government in May, 1861. Mr. Hawkshaw (Past President Inst. C.E.), who had previously reported on the railways by order of Government, was appointed consulting engineer, and in September, 1861, a contract was entered into with Messrs. Brassey and Wythes for the execution of the works, which were com-menced early in 1862, under the direction of Mr. Walmsley Stanley, M. Inst. C.E., as chief resident engineer, and of Mr. Longridge, as agent for the contractors. The North line, starting from the central station at Port Louis, traversed northern and north-eastern portions of the island, and was 31 miles in length; while the Midland line, commencing at the same station in Port Louis, passed nearly through the centre of the island, and was 35 miles in length. The only work of importance on these railways was the

\* Read before the Institution of Civil Engineers.

Grand River Viaduct, a description of which had already been given to the Institution (Minutes of Proceedings, Inst. C.E., Vol. XXV., p. 237). The North line was opened for public traffic on May 24, 1864, and the Midland line, on October 19, 1865 Land had been purchased, and all the masonry had been built for two lines of way; but at present the ironwork for the superstructure of the under girder bridges and the permanent way had only been pro-vided for a single line. The total cost of those railways had amounted to £21,876 per mile

The character of the gradients on the Midland line would be understood from the following summary :- From Port Louis to the summit there was a rise of 1,817ft., the distance being about 16 miles, or equal to an average gradient of 1 in 46.68; and from the summit to Mahebourg, a distance of about 19 miles, there was a descent at the rate of 1 in 55.61. For about 12½ miles before reaching the summit the inclination was on an average 1 in 41·17, and thence, for about 13½ miles, the line fell on an average 1 in 45·06. The steepest gradient was 1 in 27, of which there was a total length of 13,526ft., the greatest continuous length of this gradient being 6,163ft., and the next longest 5,016ft The next in severity was 1 in 30, the total length being 9,526ft., the greatest length of this gradient being 3,000ft., and several lengths of about 2,000ft. each. The ascending gradients warled from 1 in 27 to 1 in 60, while the descending gradients, towards Mahebourg, varied from 1 in 30 1 in 60. The curves varied from 950ft. radius to 6,000ft. radius, and the lengths of these curves ranged from 200ft. to 8,200ft. The ordinary radii were generally from 2,000ft. to 3,000ft. The sharpest radius which occurred on the steepest gradients of 1 in 27 and 1 in 30 was 1,600ft.; the greatest continuous length of this curve being 900ft on the former gradient, and 1,930ft on the latter. The next radius in severity was 2,000ft on the maximum gradient of 1 in 27, the greatest continuous length of this curve being 1,000ft. Reverse curves of this radius, 1,920ft. in length, were also found on the maximum inclination of 1 in 27. On descending from the summit to Mahebourg, the line from the 17th mile to the 19th mile might be said to be composed wholly of reverse curves; and at the 29th mile the radius was only 1,400ft., the length of this curve being 1,980ft., chiefly on a gradient of 1 in 30. Of curves under 2,000ft. radius there was an aggregate length of 21,165ft.; of those ranging from 2,000ft. to 4,000ft. radius there was a length of 49,710ft.; and of curves from 4,000ft. to 6,000ft. (the greatest radius), there was an aggregate length of 25,560ft., the total length of curves being 96,435ft., and of the straight portions of the line 89,467ft.

The locomotives furnished under the original

contract for working these inclines were seven in number, and of the following description:—They were tank engines, having cylinders 16in. in diameter, with a length of stroke of 22in.; the wheels, six in number, were 3ft. 6in. in diameter, and were all coupled, the length of the wheel base being 15ft. When supplied with water and fuel, these engines weighed nearly 37 tons, and they were worked with a pressure of steam of 120lb. per square inch. Subsequently, six larger saddle-tank locomotives were designed by Mr. Hawkshaw, having the following dimensions :- Cylinders 18in. in diameter, with a length of stroke of 24in.; the wheels, eight in number, were 4ft. in diameter, and were all coupled, the length of the wheel base and were all coupled, the length of the wheel base being 15ft. 6in. When supplied with water and fuel, these engines weighed nearly 48 tons, and they were worked with a pressure of steam of 120lb, per square inch. The centre pairs of wheels (one of which was the driving pair) were fixed stiff on the frame; but in order to pass easily round the curves, both the leading and the trailing wheels had \$\frac{3}{4}\$in. play on each journal, and the joints of the coupling rods, connecting these wheels with the driving pair, were fitted with a ball and with the driving pair, were fitted with a ball and socket, so as to allow the requisite motion. All the engines were manufactured by Messrs. Sharp, Stewart, and Co., and worked very satisfactorily. These engines would, with passenger trains, take five carriages and one brake-van, equal to a load of 42 tons, though on some occasions they had hauled eight loaded vehicles, weighing in all about 56 tons; while with goods trains the usual load with the lighter locomotives was 70 tons, and with the heavier locomotives from 100 tons to 120 tons. should, however, be stated that by reducing the lead of the slide valves to lin., the power of these engines had recently been increased 10 per cent. The average speed of the passenger trains, including stoppages, was 12 miles per hour between Port Louis and the summit, and 15 miles per hour from Mahebourg to the summit; while that of the goods

trains was about 9 miles an hour, including froquent stoppages. The particulars of a trip made on December 12, 1867, when the fuel and water The particulars of a trip made were noted more accurately than usual, were From these it appeared that the train consisted of ten loaded waggons, weighing together 83 tons, or, with the engine, a gross load of 131 tons; the average speed from Port Louis to the summit was 11 miles per hour, and taking the average pressure of steam in the cylinder as 60lb. square inch, the power exerted would be  $131 \times 60 \times 11 \times 88$ = 230-horse power, or not

88,000 including the weight of the engine 146-horse power, and this divided by the weight of the locomotive was equal to 3.04-horse power per ton of motor. The coal used on the above trip was obtained from Sydney, N.S.W., and the consumption amounted to 4.75lb. per horse power per hour, 8lb. of water being evaporated by 1lb. of coal, but ordinarily only 74lb. of water being evaporated by 1lb. of this coal.

With the exception of the first-class carriages. all the others on this railway had a brake on every wheel, worked from the inside. The ordinary passenger trains were composed of one first, one second, and two third-class carriages, with one brake-van, and to these trains Mr. Clark's continuous brake was attached. This apparatus was worked by a chain, which tightened the brakes on every one of the wheels simultaneously. The brakes were taken off by heavy counterbalance weights, resting longitudinally over the chain in the centre of the carriage, between the front and end wheels. This apparatus was sufficiently powerful to lock every wheel, and had worked satisfactorily; for during two years there had not been a single fracture of the chain, nor of any of the working parts. It, however, required careful management, and must be applied gradually before the train had acquired serious momentum. The brake-van of every passenger train was now provided with sand boxes leading to the rails, as formerly the dew on the rails wetted the wheels of the brake-van, and prevented the friction rollers of the apparatus from revolving; whereas, as soon as sand was applied, the wheels became dry, and the friction rollers acted efficiently. Every train of four or five carriages had two guards, one to work the continuous brake, the other to use the separate brake, if necessary, attached to that carriage which was not connected with the continuous The heaviest passenger train which had descended from the summit to Port Louis consisted of fourteen carriages and two brake-vans, conveying 513 troops. This was on November 14, 1868, and it was kept perfectly under control by the continuous brake on four carriages, and by five additional brakesmen, the speed being steadily maintained at 20 miles per hour. There were but four instances of passenger trains getting for a time beyond control:—First, one morning when the rails were wet, a train descended from the summit for a distance of 33 miles in five minutes, or at a speed of 45 miles per hour. This was the highest speed on record, and it occurred before the sand boxes were put on the brake-vans. Secondly, in a similar way, another train attained a speed of 32 miles per hour. Thirdly, a train over station for a considerable distance, chiefly from the want of sufficient care on the part of the engine-driver and guards. Lastly, a train once attained an excessive speed in descending from the summit, through the dropping off of the nut of the eyebolt passing through the axle on which the continuous chain of the brake apparatus was wound. The speed in descending the inclines was limited theoretically to 18 miles per hour, practically it rarely exceeded 25 miles, and the carriage brakes were generally sufficient to control the train, without the necessity of applying the engine brake. The goods trains in descending the inclines, as a rule, consisted of eight loaded waggons with the lighter locomotives, and of ten or twelve waggons with the heavier engines; and in these cases also the brakes on the waggons, two being screw brakes and the remaining waggons being furnished with the ordinary lever brakes, afforded power sufficient to control the trains. It had long been in contemplation to make safety sidings at the foot of the steepest inclines, but the ground was by no means favourable for the purpose, and, moreover, it was feared that such sidings might become a source of danger.

The rules in force for the regulation of the traffic given in detail, as well as the traffic returns for the years 1866 and 1867, the rates for passengers and goods, and the statement of the receipts an pressure upon the warp beam, by which means, tenon the main line and at the stations were then given in detail, as well as the traffic returns for

expenditure for the year 1866, from which latter it appeared that the working expenses were then 621 per cent. of the receipts; but this result was said to be due to several exceptional causes. sidering the high price paid for skilled labour and for fuel, the agricultural character of the district through which the line passed, the severity of the gradients, the want of anything that could be called a town, save at Port Louis, the lack of minerals or manufactures to transport, the peculiar nature of the sugar traffic—requiring a large amount of rolling stock for three months in the year, whereas, for the remaining nine months less than half the quantity sufficed—the author thought it was not surprising that the working expenses of the Midland line should in 1866 have been 62½ per cent. of the receipts, or 5s. 5d. per train mile. Now that the heavier locomotives enabled a larger amount of sugar to be carried, and when the goods traffic was further developed, it was believed a considerable decrease in the percentage of working expenses to receipts would ensue, accompanied was hoped, by a reduction in the cost per train mile.

In conclusion, it was remarked that, although it might sometimes be impossible to construct a railway with easier gradients than those on the Mid-land line, yet the difficulty of working these inclines in wet weather had been so great, the load hauled so small, and the speed so low, that the author thought the severity of any gradient for a long rise should never exceed 1 in 40; and that it would always be preferable (under the ordinary system of tractive power), to incur, within reasonable limits, any additional expense that might be requisite to bring the inclination within this ratio. requisite to bring the inclination within this ratio. It was also suggested that in laying out such inwhatever might be the ruling gradient (provided it was not entirely exceptional, and where additional power could be applied), that gradient should be followed throughout the line, as far as the features of the country would permit It was likewise recommended that pieces of level should be introduced between the different inclinations, as they were of the greatest value in controlling the trains in descending. The Midland line had now been opened for more than three years, and, fortunately, no accident had yet oc-curred to any train in descending the inclines.

The appendix contained a summary of the gradients and curves, the details of the locomotives and schedule of the rolling stock, the imports and exports in Mauritius from 1860 to 1866, the population, revenue and expenditure of the island, and the immigration returns between the same dates, a memorandum of the steam machinery and of the value of labour and materials in the island, and meteorological observations taken at Port Louis in

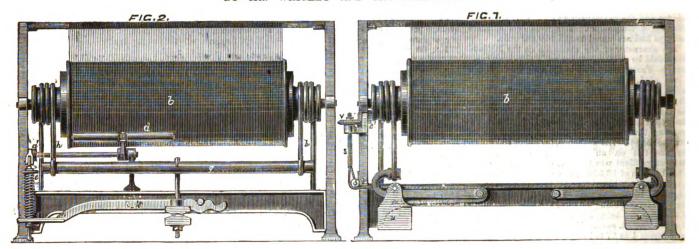

#### ADJUSTING THE TENSION OF WARPS.

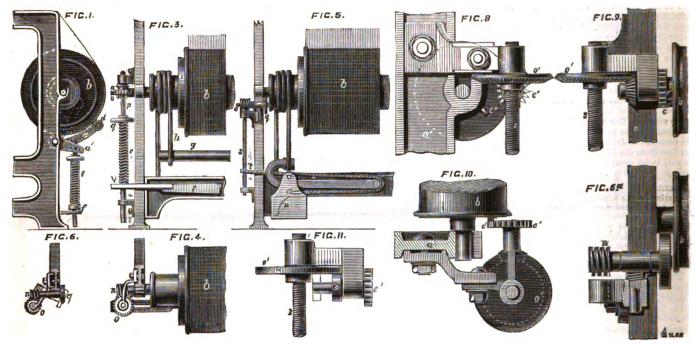

IN weaving, the usual method adopted for adjusting the tension of the I ing the tension of the warps as the warp beam becomes reduced in diameter, is by the opera-tive moving the weights (giving tension to the warps) upon the levers towards the fulera of the same as the yarn is run off the beam. This plan has been improved upon by an invention which has been patented by Mr. Thomas Wrigley, the has been patented by Mr. Thomas Wrigley, the engineer, and Mr. John Richardson, the secretary, of the Loom Improvement Company, Manchester. Their invention is designed for the purpose of regulating and maintaining at one uniform tension, the warp threads of looms as they are delivered from the warp-beam, by self-acting means. This regulating motion may be accomplished by several equivalents, according to the class or style of loom for which it may be required. We will, therefore, proceed to describe the various arrangements and adaptations of mechanism for which these motions are designed.

Figs. 1 and 2 of our engraving represent respectively a side and back elevation of one arrangement of self-regulating mechanism adapted to a loom supplied with a spring and lever motion employed for giving tension to the warps. In these views, a a 1 is a double lever, supported by and having their fulcra in the loom framing a little below the bearing of the warp beam b; the long lever or arm a of this double lever is provided with a flat presser or roller d, which is bedded against and kept in contact with the warp threads upon the beam b through the medium of the spring e, which is connected with the short lever or arm a ! of the double lever, the lower end of the spring being in torrible contact with the lever f, through the medium of

#### ADJUSTING THE TENSION ARRANGEMENTS FOR OF WARPS.

BY MR. WRIGLEY AND MR. RICHARDSON.

sion is given to the warp threads. It will be seen on reference to figs. 1 and 2, that when the warp beam b is full and at its greatest diameter, the spring e is at its greatest compression, thereby spring e is at its greatest compression, thereby exerting its maximum pressure upon the apparatus, giving tension to the warps at the time the warp beam is at its greatest diameter. Now, as the warp beam b delivers its yarn, it gradually becomes reduced in diameter, which being followed by the roller or presser d to its smallest diameter, shown in dots, figs. 1, gives a compensating reduction (through the medium of the double lever c) to the pressure exerted by the spring transmitting tenpressure exerted by the spring transmitting tension to the warps. Thus it will be seen that the pressure of the spring e is gradually reduced in proportion as the warp beam grows less during the time it is delivering its yarn, thereby maintaining throughout from the greatest to the smallest diameter of the warp beam one uniform and even tension.

Figs. 3 and 4 represent a detached back elevation and plan view of another modification of apparatus for effecting through the spring and lever a uniform tension to the warps. In these views, the end of the shaft supporting the warp beam b is provided with a worm n, and gears into a worm wheel o, the boss of which forms a nut that actuates through the medium of a hyperbolic property of the state of the sta thread upon the spindle p, a gradual extension between the surfaces q, and v confining the spring e, and through which tension is transmitted to the warp beam. In this arrangement, when the warp beam is full, the spring e is at its greatest com-pression, so that the slow revolution of the beam as it delivers its yarn transmits motion through

the worm n to the wheel o, whilst revolving on the thread of the spindle p, raises it so as to extend the surfaces between which the spring e is confined, thereby gradually reducing the pressure upon the beam as it delivers its yarn.

Figs. 5 and 6 represent a back elevation and plan view of a self-regulating motion applied to looms, for adjusting and moving the ordinary weight upon the levers, giving tension to the warps in accordance with the delivery of yarn from the beam. In these figs., q is a friction wheel, which is kept in contact with the shaft of the warp beam through the medium of the spring r. This wheel q, as the shaft of the beam revolves, gives motion to the worm n and worm wheel o, which being keyed to the vertical shaft s, causes the shaft as it slowly revolves to coil or wind upon it the cord t, which being connected to the weights u gradually draws or moves them nearer to the fulcrums of their respective levers, in proportion as the yarn is delivered from the beam, thereby uniformly main-taining the tension of the yarn. This arrangement taining the tension of the yarn. This arrangement is shown enlarged at fig. 6°. The friction wheel q, when in its place, and driven by the shaft of the warp beam, is locked by reason of the square head of the swivel stud encircled by the spring r being pressed into the socket, in which, when raised, the bracket supporting the friction wheel is allowed to swivel or turn, as seen in dots, fig. 6, in which position it is removed out of contact with the shaft of the beam, and in which position also the worm n is removed out of gear with the driven worm wheel o, or the square head of the swivel stud may be formed on the lower portion, which allows it, when the friction wheel is in contact with the beam shaft, to be raised by the spring so as to be locked. By this arrangement, the operative depressing the friction wheel would be enabled to swivel or turn the wheel out of gear, and also out of contact with the beam shaft.

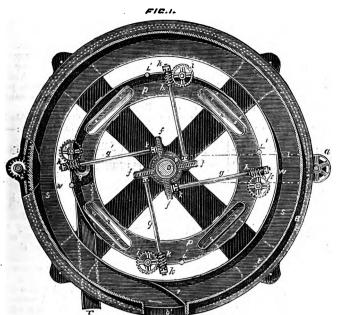

In fig. 7, an intermittent arrangement of driving is shown for moving the weight for regulating the tension of the warps. Bevel gearing v is employed in lieu of worm and wheel. The shaft s transmitting the sliding motion to the weight, in this instance, is caused to rise by reason of a screw in the wheel v, the action of which draws the cord t along wheel v, the action of which draws the cord t along with it, thereby giving the required sliding motion to the weights u u, the effect of which regulates the tension of the warps, as described.

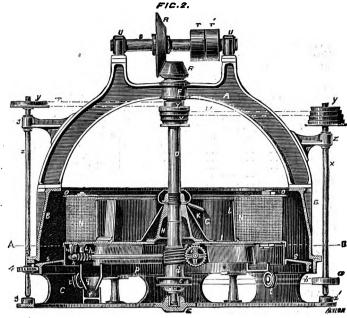

Figs. 8, 9, and 10 represent respectively side, back, and plan views of a self-acting regulating motion, which may be applied for easing the spring e for explicit the tension, or it may be explosed for

which may be applied for easing the spring e for regulating the tension; or it may be employed for actuating the ordinary weights for the purposes described. In these figs.,  $a^1$  is the framing of the loom, b the beam in which a stud or projecting pin  $c^1$  is placed. This stud with every revolution of the beam as the yarn is delivered, comes into goar with one of the teeth in the star wheel  $e^1$ . This wheel, as it is thus caused intermittently to revolve gives motion to the beau wheels  $e^1$  the to revolve, gives motion to the bevel wheels o 1, the revolution of which may be arranged so as to release the pressure of a spring, giving tension to the yarns, or they may be employed for raising a vertical shaft connected to cords, giving motion to the weights, also regulating the tension. The motions so transmitted, whether for releasing the pressure of a spring or removing weights, will regulate the tension of the warps in accordance

#### IMPROVED CENTRIFUGAL MACHINE.

BY MR. J. F. BRINJES.

with the delivery of yarn from the warp beam. Fig. 11 represents an arrangement of adjustable friction gearing to be employed for driving the vertical shaft s.

#### IMPROVED CENTRIFUGAL MACHINE.

THE accompanying engraving illustrates some substantial improvements in centrifugal machines, which have recently been patented by Mr.

J. F. Brinjes, of Fieldgate-street, Whitechapel.

His aim is to enable these machines to be worked continuously, or without stoppages for the intro-duction of the substances to be operated upon, and for their subsequent discharge. By this means, considerable economy in time is effected, and the great wear and tear hitherto attendant upon the frequent stoppage of the machine is prevented.

Another great advantage afforded by these improvements is the continuous self-cleansing by eentrifugal action of the wire gauze or perforated metal forming the straining medium of the drum, without the necessity for using water or steam

without the necessity for using water or steam jets, brushes, or other appliances.

In our engraving, fig. 1 represents a sectional plan of one form of the improved centrifugal machine as adapted for use in the manufacture of sugar, the section being taken along the line A of in fig. 2; fig. 2 is a sectional elevation of the same machine. A is the main framing, resting upon the circular casing B, which is bolted down upon the bed or foundation plate C. D is the main vertical shaft working at its lower end in the footvertical shaft working at its lower end in the footstep bearing E in the base plate, and, at its upper end, in a collar bearing F in the main framing A. This shaft carries the revolving drum G, which is secured to it by the cast-iron boss H bolted to the bottom plate I of the drum, a sheet metal cone K being fitted around the boss for the purpose of deflecting outwards the sugar as fed into the centre of the drum. Near the circumference of the plate I which forms the lower portion of the drum, there are fitted an even number of upright spindles L. L. 1, carrying rollers or pulleys M. M. 1, over which are stretched the endless wire cloths N. N. which constitute the perforated walls or sides of the drum.

the drum.

One of the rollers marked M in each pair serves as the actuating or driving roller of the endless cloth which passes partly round it, whilst the other roller (marked M 1) acts simply as a carrying roller, and may revolve loose on its spindle. Each driving roller M is fast on its spindle L, which rotates on its own axis during the revolutions of the drum. The upper ends of the several spindles L L 1 pass through the top annular plate O of the drum, which plate is bolted down on to upright standards or brackets P of the desired height, the brackets being secured to the lower plate I of the drum. A sufficient space or opening Q is left between the contiguous rollers M M 1 of each adjoining pair for the discharge of the sugar as fast joining pair for the discharge of the sugar as fast as the syrup or liquid has been expelled therefrom

through the straining material, the discharge and supply both taking place continuously during the revolutions of the drum, and hence stoppages are obviated.

The main vertical shaft which carries the drum is actuated by the bevel frictional goar R and driving shaft S, provided with fast and loose driving pulleys T T <sup>1</sup>, and working in the bearings U U cast pulleys T T  $^1$ , and working in the bearings U U cast on the main framing A. Just below the collar bearing of the upright shaft there is keyed the coned driving pulley V, from which a strap W transmits a slower motion to the vertical shaft X through the reversed cone pulley Y fast on the upper end of it. This shaft X works in the collar and footstep bearings Z Z  $^1$ , and carries at its lower extremity the driving pulley a, which, by means of the belt b and pulley c, imparts rotatory motion to the short tubular shaft or collar d which turns freely round and upon the lower end of the main vertical shaft D, but at a slower rate than the restrict young and upon the lower end of the main shaft. D, but at a slower rate than the main shaft. This collar d has a worm or endless screw e formed thereon, which gears into the worm wheels f f fast on the inner ends of the horiwheels f f last on the inner ends of the last containing the spindles g g for driving or actuating the spindles L L of the rollers or pulleys M M which actuate the endless wire cloths. For this purpose, an endless worm h is fitted to the outer end of each of the horizontal spindles g, these worms gearing into worm wheels i i keyed on to the lower extremities of the spindles L L of the driving rollers M M, and thereby imparting a slow rotatory motion thereby, and causing the endless wire cloths to travel slowly round their rollers during the revolutions of the drum G. k k are bracket bearings for carrying the horizontal spindles g g, these bearings being secured to the under side of the bottom plate I of the drum and revolving with it. l lare a series of radial guiding channels (one for each endless travelling wire cloth), the sides being secured to the bottom plate of the drum, and so disposed and contracted at their outer ends as to guide the sugar to be operated upon against the rear end of each of the travelling wire cloths which, when the drum is revolving, travel in the direction shown by the arrows, and carry slowly along with them the sugar until it arrives at the

openings Q Q, through which it is discharged.

During the time occupied by the sugar in travelling from one roller M to the other roller M 1 of communicates with an annular reservoir 9, from the endless wire cloth, the syrup or other liquid is being expelled therefrom through the wirework by the centrifugal action of the drum. By varying the speed of the travelling motion of the wire cloths, the sugar may be submitted to the centrifugal action of the drum for a greater or less period according to requirement. This adjustment or regulation of the speed of travel of the endless wire cloths is effected simply by changing the driving strap or belt W from one sized pulley to another, by which means the speed of the main driving worm e is varied, and a corresponding motion of the endless wire cloths. The syrup which is expelled through the inner half 1 of the \$\mathbb{X}\$?26,000, the company to pay its own costs.

cloths is directed against a inclined plate m, which is fixed between the rollers M M <sup>1</sup> of each pair of rollers, and between the inner half 1 and outer half 2 of the endless wire gauze cloth N.

Whilst the inner portion 1 of the wire gauze is perating as a straining medium, the outer portion 2, which is travelling of course in the opposite direction to the inner portion 1, is being cleansed by the action of the centrifugal force alone, which readily expels or removes any solid substance which may be adhering to the gauze. This operation is greatly assisted by the fact that the position of this part of the gauze is reversed, that surface which was previously next to the interior of the which was previously next to the interior of the drum being now on the exterior, and, consequently, the adhering matter, in lieu of requiring to be forced through the gauze, is removed from the same side of the gauze as that by which it entered.

n n are vertical spouts, connected with suitable apertures o o made in the bottom plate I of the drum, for the purpose of directing the separated liquid into any convenient receptacle. Mr. Brinjes prefers, however to collect such liquid in an inquid into any convenient receptacie. In Finnes prefers, however, to collect such liquid in an annular trough p, the bottom of which is inclined, and has a discharge opening q at its lowest part, which allows the liquid to flow out into an inclined trough r which conveys it away to any desired locality. The sugar, on being discharged through the openings Q Q, is received on a revolving annular table s, supported upon grooved antifriction rollers t carried by studs bolted to the side of the base plate C. w is an annular guard plate attached to the inner circumference of the revolving table s for the purpose of preventing the sugar from gaining access to the driving gear underneath the bottom of the drum.

A rotatory motion is imparted to the annular table s by means of the strap w, pulleys y y, and vertical shaft z, which latter works in the bearings vertical shaft z, which latter works in the bearings 3 3, and carries a spur pinion 4 gearing into corresponding teeth 5 formed on the outer periphery of the annular table. A discharge opening  $b^1$  is made partly in the casing B and partly in the base C, through which the sugar carried round on the table s is directed by means of the fixed inclined guiding plate 7. A pipe and stop cock serves to supply liquor or water as may be required; it communicates with an annular reservoir 9, from which reducts pipe 10 provided with perfected

ON THE SUBMERSION AND RECOVERY OF SUBMARINE CABLES.\*

BY PROFESSOR FLEEMING JENKIN, F.R.S.

THE speaker began by stating that his object was to explain the principles on which engineers had acted in laying and recovering sub-marine cables, rather than to exhibit the details of the machinery employed. The general construc-tion of electrical cables was first described, and specimens were shown; especial attention being drawn to the deep sea French Atlantic cable, consisting of the following parts:—A copper conduc-tor, gutta-percha insulator, and jute serving, surrounded by ten wires of homogeneous iron, each served with five Manilla yarns saturated with tar.

TABLE L.—CONSTRUCTION OF FRENCE ATLANTIC

Breaking Strain.—lbs 644

Strength in tons ... ... 7% tons.

Table No. 1 gives the dimensions, weights, and strengths of each of the component parts. The wire served with hemp will bear a greater weight wire served with hemp will bear a greater weight than the sum of the weights borne separately by the wire and the strands; and, again, the ten served wires, when formed into a rope, bear a greater weight than the sum of the weights which each will bear. Moreover, while the homogeneous from elongates less than 1 per cent. before breaking, and the hemp elongates only 0.75 per cent., the two combined stretch 3 per cent. This paradoxical result is due to want of absolute uniformity in the strength of each part; when separate, each breaks at the weakest point; when combined, the weakest points seldom coincide; hence, the strength of the combination is the sum of the mean strengths of the parts, necessarily greater than the sum of the minimum strengths. The so-called spiral or helical form does not really render the cable elastic or liable to stretch, nor does it compress the core inside the sheathing, as was shown by an experi-ment where the core was actually withdrawn without causing the collapse of the sheathing.

The manner of coiling the cable on board ship was explained by diagrams and models; it being shown that, in order to avoid putting a twist into the rope when taking it out of the hold, it was necessary to put a twist in when coiling it away. Bad coiling produces kinks or loops drawn tight, which are avoided by a cone filling the eye of the coil, and by rings or equivalent arrangements preventing the bight as drawn out of the hold from lashing out under the influence of centrifugal

The following table gives the dimensions and contents of the "Great Eastern" tanks as arranged for the Atlantic expedition. These tanks keep the cable under water on board ship to facilitate the electrical tests. They carry a weight of 5,000 tons in a bulk of 180,000 cubic feet, the tanks not being in a bulk or 100,000 filled quite to the top. TABLE II.

size, these tanks occupy a very insignificant proportion of the whole bulk of the "Great Eastern."

Mr. C. W. Siemens has for light cables employed a sort of reel or drum on a turntable with partial success, instead of the fixed tank and coil. From the tank, the cable, when paid out, passes over a pulley and along a trough to the brake drum, the object of which is to restrain the free exit of the cable to such an extent as is desired. The cable is laid hold of by being passed several times round a drum, as a rope making fast a vessel may be seen to be passed round a bollard; the friction allows a slight strain at one end to prevent a very heavy pull at the other end from causing the rope to slip round the drum. The slight pull at what may be called the light end of the rope is given by a series of jockey pulleys which play the part of the hand when the rope is allowed to slip round a bollard, but, in paying out a cable, the rope does not slip

round a drum; the drum itself turns round restrained by a friction band or belt.

It is essential that this restraining friction should be constant—a result obtained by the Appold brake, which was explained by models and diagrams. In this arrangement both ends of the

 $P = \omega \cos \phi$ ; perpendicularly to itself, where v is the velocity of the ship.

hence, 
$$\cos \phi = \frac{v_{11}^2}{v_1^2} = \frac{v^2 \sin^2 \phi}{v_{12}^2},$$
and  $v_1 = \frac{v \sin \phi}{V \cos \phi};$ ...... 1deg.

and, assuming that the resistance is preportional to the square of the velocity, we have  $\omega = q v_1$ and hence.

$$\frac{\omega}{q} = \frac{v^2 \sin^2 \phi}{\cos \phi}, \text{ or }$$

$$\frac{\omega}{q v^2} = \frac{\cos \phi}{\sin^2 \phi},$$

from which we have

$$\cos \phi = \frac{\sqrt{\omega^2 + 4 m^2} - \omega}{2 m} \dots 2 \deg$$

where  $m = q v^2$ .

was going at the speed of six knots per hour, lay at an angle of 6 deg., so that the inclined plane was seventeen miles long, and each foot of the cable took nearly three hours to reach the bottom

The strain T at the top of the inclined plane, if there were no friction preventing the rope from slipping back along the plane, would be equal to the weight of a piece of cable hanging plumb from

where w is the weight per foot run of the cable and w is the depth in feet.

brake strap are attached to one lever, in such a manner that when the drum begins to turn it tends to lift the lever and weight hanging to it, and as the lever is lifted it slackens the brake strap until the difference of tension on the two ends of the strap is equal to the weight hanging on the lever. When this is the case, the lever is no longer lifted but remains stationary with the strap, allowing the drum to turn, restrained by a con-stant fraction equal to the weight on the lever. If the coefficient of friction increases, the lever will be a little more lifted and the strap slackened; if the coefficient of friction diminishes, the lever and weight will fall, tightening the strap; but in any case the retarding force will be simply equal to the weight.

From the brake drum the rope dips under

a weighted pulley, which rides as it were suspended on a V of taut cable; if the strain increases, the rope straightens and raises the pulley. if the strain diminishes, the weight and pulley fall; thus the height of the pulley indicates the strain. This instrument is called the dynamometer. Lastly, the rope passes over a pulley into

Having shown how the cable was treated, the speaker proceeded to show how the strains to be expected could be calculated. A cable paid out in air hangs in a catenarian curve, but in water lies in a straight line, and the strains in the two cases are wholly different. In air, the rope meets with no sensible obstacle to its motion, either longitudinally or in a direction perpendicular to its own length; in water, on the contrary, each foot of a cable meets with an opposition to its motion perpendicular to its length, which we may call q, and for the Atlantic cable

q = 0.154 v 2. where v is the velocity of the cable normally to its own length in feet per second. Thus, as the cable weighs 0.2575lb. per foot, it cannot sink faster

weighs 0.25751b. per foot, it cannot sink faster than the speed given by the equation
0.2575 = 0.154 v 1²,
from which v 1, the settling velocity, is found to be
1.294ft. per second, or 0.765 knot per hour. The result of this resistance to displacement is that the cable lies in a straight line, not in a catenary curre, supported, as it were, by an inclined plane of water constantly yielding at the velocity v<sub>1</sub>. The inclination of the straight line depends on the velocity of the ship and on  $v_1$  not being at all

affected by the tension of the rope.

The angle  $\phi$  at which the cable will lie may be calculated as follows :- Let P be the resistance of the water to displacement by each foot of the cable of the weight  $\omega$  when lying at the angle  $\phi$ ,

let  $v_{11}$  be the velocity at which the cable moves

 $v_{11} = v \sin \phi$ 

Also 
$$P = \omega \frac{v_{11}^2}{v_{12}^2};$$
hence,  $\cos \phi = \frac{v_{11}^2}{v_{12}^2} = \frac{v^2 \sin^2 \phi}{v_{12}^2},$ 

cos. 
$$\phi = \frac{\sqrt{\omega^2 + 4 m^2} - \omega}{2 det}$$

From this formula, as indeed from common sense, it appears that the greater the value of q and of v the smaller the inclination with the horizon. The rough Atlantic cable when the ship

the surface of the water to the bottom, or  $T = \omega \sigma$ 

But there is a sensible friction which helps to relieve the strain precisely as when a chain is lying on a solid inclined plane; calling  $m_1$  the colying on a solid inclined plane; calling  $m_1$  the coefficient of friction in pounds per foot length of cable at the velocity v in feet per second, and assuming that  $m_1 = q_1 v^2$ , the experiment of the Atlantic cable showed that  $q_1 = .00504$  (this is equivalent to 0.81 cwt. per knot of cable when slack is paid out at the rate of one knot per hour). The result is, that when slack is paid out, say at the rate of one knot per hour, and when  $\phi =$  6.45deg., the strain is diminished by one-half, and if slack were paid out at the rate of 1.4 knot per and when  $\phi =$ 

require no retarding force whatever.

The strain T 1, when the velocity of the cable is v 111, can be found from the following formula:

T<sub>1</sub> = 
$$\omega s - m_1 \frac{\left(\frac{v_{11}}{v} - \cos \phi\right)^s}{\sin \phi}$$
 sin. 8deg.

Cables of light specific gravity have a small settling velocity and lie at great length in the water, and, if they are also rough, the coefficient water, and, it they are also rough, the coefficient q 1 may easily be so great as to relieve the brake of most of the strain which would be necessary to lay a cable of equal weight but small bulk and smoother surface, with the same amount of slack. If no slack were laid, there would be little difference between the tension required for cables of different construction but of equal weights in water. When much slack is laid, all cables will water. When much slack is laid, all cables wur be considerably less strained than if laid without slack; and, finally, the faster the ship goes the less slack is required to produce any given amount of relief.

The correctness of the above theory has been amply proved in practice. If in seas 2 miles deep the cable hung in a catenary 12\frac{3}{2} miles long, the weight to be carried would be  $8\frac{1}{2}$  tons, and the strain on the cable 29 tons; while, if the cable hung in a catenary, the inclination of which to the horizon at the stern was 9deg. 30min., the length would be 24 miles, the weight 17 tons, and the strain 102 tons instead of about 14cwt.—the strain actually observed for the Atlantic cable when being paid out at 7 knots per hour while the ship was going at 6 knots per hour. The rise and fail of the ship, even in heavy weather, very alightly affects the strain while paying out, on account of the slight inclination of the cable to the horizon. The margin of strength in deep sea cables of the Atlantic type is even greater than is given in most engineering works, since the cable will bear tenfold the strain which is found necessary in lay-

tenfold the strain which is found necessary in laying.

The process of grappling was next described, and the operation illustrated, by dragging a ministur grapnel over the floor, so as to hook a chain lyin, there. When the cable is hooked, the strains o the grapnel rope are simply the weights of the bight lifted, and the length of this bight depends on the slack. Thus, with 14 per cent of slack, the length of the cable lifted will be 4.89 times the depth to which it is raised. Thus, in two miles of water, about 9.8 miles of cable will be lifted, the weight on the grapnel will be 6.86 tons, but the strain on the cable will be only one component of this weight resolved in the direction of the tangent to the curve at the grapnel; this strain will be 5.5 to the curve at the grapnel; this strain will be 5.5 tons. Thus, it is clear, that in calm weather, with 14 per cent. slack, the cable can be lifted from a depth of two miles. This was actually done upon one occasion; but owing to pitching of the ship the cable parted, and was successfully recovered by the obvious device of grappling the cable in two points about 24 knots apart, and breaking the cable at the point furthest from land; the loose end then hung down over the other grapnel, and it is obvious that by this plan the strain on any cable in any depth can be limited to the simple weight of a length of cable hanging from the surface to the bottom. The Atlantic cables will bear five times the strain due in this manner to two miles of depth, and for this operation the margin of strength is also ample. The cable is hauled in by machinery very similar to that adopted for paying out; the drum being simply turned in the opposite direction by a steam engine, if only a small length is to be picked up. If many miles are required, the cable is transferred to the bow, and hauled up by a double drum to avoid the fleeting necessity on a single drum. The friction on the water during the opera-tion, adds to the strain; thus, with the valve of q 1 previously found, at one mile per hour, the friction per mile would be 0.81 cwt., adding in a depth of two miles 1.61cwt. to the strain due to the simple weight; besides this, there is some resistance due to the displacement of the water, by the hight of drum. The friction on the water during the opera-

\* Read before the Royal Institution.

the rope at the bottom, and some extra weight due to the fact, that the cable hangs in a catenary, not in a straight line. The length of this catenary depends on the rate at which this cable is hauled through the water; but even after allowing for all these things, the strength of the cable is from three to four times greater than the strain which in fair weather need come on the cable when being picked up from a depth of two miles-a margin of strength not unfrequently adopted even in permanent engineering works.

It was by calculations like these, that before the It was by calculations like these, that before the 1865 cable had been recovered in 1866, the speaker was able to write in "The Times," of August, 1865, "If the cable retain its strength, as it probably will, it can certainly be raised;" and now that experience has confirmed theory, engineers are justified in looking forward with great confidence to the continued prosperity and extension of deep-sea telegraphy. The following tables give some further information as to the French Atlantic cable about to be laid, which will cover fifty acres of ground, being be laid, which will cover fifty acres of ground, being De laid, which will cover hity acres of ground, being a narrow strip, 3,564 knots long, and a little more than an inch wide.

#### THE CHANNEL RAILWAY BRIDGE.

THE CHANNEL RAILWAY BRIDGE.

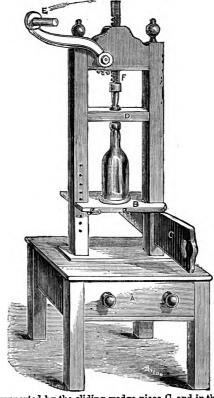

It is announced in the "Moniteur" that His Majesty the Emperor, accompanied by General Ge Failly, went to the Depot des Marbres, to examine the models for the great bridge over the Straits of Dover, on Tuesday week. M. Boutet carefully explained to His Majesty the various details connected with the construction. The Emperor, with a view to convince himself of the value of the system, stood upon one of the little models, and expressed himself astonished at the incredible rigidity which it possessed in every respect, and the relative lightness of a locomotive and tender constructed on the scale of the bridge. His Majesty then proceeded to examine the little bridge intended for the school at Vervius (Aisne), and walked over the footbridge which is almost finished, and which is to unite the Senlis promenade with the railway, afterwards turning his which is almost finished, and which is to unite the Seniis promenade with the railway, afterwards turning his attention to the mode of making the cables and trusses, questioning M. Boutet very closely and with much interest as to the facility of execution, and the great economy that will result from the application of the system to the construction of bridges in general. Before leaving, the Emperor went into the offices to see the large plans of the Channel Bridge, the details of which were carefully examined. His Majesty put several questions as to the expansion and Before leaving, the Emperor went into the offices to see the large plans of the Channel Bridge, the details of which were carefully examined. His Majesty put several questions as to the expansion and oxidation of the metal, as to the means of verifying the form of the bed of the sea, so as to facilitate the fixing of the piles, and getting them level in case the bed should be unexpectedly irregular—the questions displaying a thorough knowledge of the subject, and that he had studied the matter to its foundation. His Majesty warmly congratulated M. Boutet, and desired him to send his plans and pamphlet to him as soon as they were printed. M. Boutet availed himself of the opportunity to present Commander Porteu, of the Imperial Marine Artillery, and the promoter of a large bridge from St. Malo to St. Servan a Dinard, who, having visited Paris to consult M. Boutet on the subject, happened to be present at the moment of the Emperor's visit. Commander Porteu was very graciously received by His Majesty, who listened with great attention to his explanation of the advantages which will result from the construction of the bridge, which will be fully a kilometre in length, with but one support, at the Bizeux rock. M. Boutet showed the Emperor his plans for the said bridge, which is 20 metres in width, and is to carry a railway as well as a carriage way and pavement for foot passengers. His Majesty remarked that this would be a good application of the Boutet system, and that Commander Porteu might send him the memoir which he had prepared upon this project as soon as it was printed.

THE PEACE JUBILEE AT BOSTON, U.S. THE National Peace Jubilee at Boston commenced on Tuesday last, and will terminate to-morrow (Saturday). The jubilee is to con-

sist of the greatest musical festival ever known in sist of the greatest musical festival ever known in America, or, perhaps, in the world, and, according to the programme, will be a great noise. A huge building, called the Coliseum, capable of holding 50,000 persons, has been erected, and a chorus of 5,000 singers and an orchestra of 1,000 performers will provide the music. The chief singers of the country have volunteered their services, and the country have representations covered connections. musical programme contains several compositions prepared specially for the occasion. The programme abounds with colossal performances. Thus the overture from Wagner's "Tannhäuser" is to be given by a "select orchestra of 600 performers;" the Ave Maria sung by Parepa-Rosa is to have an the Ave Maria sung by Parepa-Rosa is to have an "introductory violin obligato by 200 violinists;" the "Star-Spangled Banner" is to be "sung by the full chorus with grand orchestra, organ, military band, drum corps, chiming of bells, and artillery accompaniment;" Meyerbeer's "Coronation March" is to be "performed by the full band of 1,000 instruments," and in the case of various popular airs, the "audience, to add to the effect, is invited to join in the singing." "Fifty trumpeters" will blow in "Fra Diavolo," and "one hundred anvils" be struck in the "Anvil Chorus," so that an idea of the stupendous scale and also the noise of the jubilee may be formed. The big drum to be used upon the occasion has The big drum to be used upon the occasion has been finished, and O'Baldwin, the Irish giant, has also been engaged to beat it. This mastodonian drum is 3ft. through from head to head; the heads are about 8ft. in diameter; for the skins, two mammoth oxen yielded up their hides, it being found impossible to procure the hide of an elephant, and upon each head is ironically painted "Let Us Have Peaco."

HEYER'S BOTTLE CORKING MACHINE.

THE annexed cut shows a very handy contrivance the invention of Mr. Heyer, of 101, Leatherlane, Holborn. The stand A carries an upright frame, in which the apparatus is held. The movable rest B is hinged on a pin at the left end, and can be raised or lowered according as long or short bottles have to be corked. The other end is

supported by the sliding wedge piece C, and in the centre is a circular swivelled plate, upon which the bottle rests. In the bar D is a brass tapering guide tube through which the cork passes, and in which it is compressed, the lower portion of the tube being corrugated vertically. The rack F is furnished with a plunger, which is brought to bear upon the cork by moving the handle E about a third of a turn in the direction of the arrow. The arrangement is simple, and enables the operation of bottling to be performed with rapidity and accuracy.

A LARGE gymnasium for the use of the troops is being erected at the Huts Encampment, Pembroke Dock. The cost is expected to be about £1,000.

THE SEWERAGE AND DRAINAGE OF BROMLEY, KENT.

THE SEWERAGE AND DRAINAGE OF BROMLEY, KENT.

YESTERDAY afternoon, a deputation from the local board of Bromley, Kent, had an interview with the Secretary of State with reference to the drainage and sewerage works in contemplation at that place. The immediate object of the deputation was to obtain a further inquiry into the merits of the scheme proposed by the board, under the advice of Mr. Arthur Jacob, C.E., who prepared the necessary plans and estimates. The inquiry was requested with the view of obtaining the sanction of a loan of £54,000, to assist in purchasing the land required for the purpose of irrigation, and carrying out the necessary works. The deputation comprised Mr. W. D. Starling, Dr. Farr, Dr. Slott, Dr. Hughes, Mr. West, Mr. Muffet, Mr. Latta, the clerk to the Board, Mr. Ryde, Mr. Chambers, and Mr. Jacob, the engineer for the proposed works. The right honourable gentleman received the deputation in his usual courteous and polite manner. He alluded to the fact that the proposed project had been most favourably reported upon by Mr. Morgan, who conducted a former inquiry on the subject. Mr. Rawlinson also fully concurred in the report of Mr. Morgan. While admitting the soundness, validity, and the engineering merits of the project, Mr. Bruce regretted that at present he was unable to give a decisive answer to the request of the deputation. He would, however, take it into consideration, and authorize a further investigation of the whole question, with especial reference to the allegations put forward by the adjoining landholders in the matter of residential damages.

#### BUILDING CONTRACTS.

BUILDING CONTRACTS.

THERE is, perhaps, no class of contracts in which greater recklessness of consequences is shown than in building contracts. When the owner of land wants to build upon it he generally chooses an architect in whom he has confidence, and then advertises for tenders for the buildings, and having chosen a contractor to do the work, he confides the superintendence of the erection of the buildings to the architect. One of the commonest terms in building contracts is, that the work is to be paid for by instalments, as it progresses, on the architect giving certificates from time to time that the work is properly done. It is also generally stipulated expressly that no money is to be paid either during the construction or on the completion of the building unless the builder obtains from the architect a certificate that the building is being built or is completed, as the case may be, to his satisfaction.

Such a stipulation as this practically leaves the builder entirely at the mercy of the architect, who is thus placed in the position of an arbitrator between the landowner and the builder. The effect of these stipulations in building contracts has more than once come before the Courts. In Clarke v. Watson (18 W. R. 345) the action was by a contractor against a landowner for payment for work done under a building contract which required (in the usual form) that the plaintiff should not be paid until the defendant's architect had given a certificate that the work was properly completed. The declaration averred that the architect withheld his certificate improperly, and claimed payment as if the certificate had been given. The Court held on demurrer that the declaration was bad, and that the improper refusal of the architect to give the certificate which was precedent to his right of action against the defendant.

This latter point arose in the case of Davis v. Taylor, in the Court of Exchequer last week. The against the defendant.

planting of the cointion that he should go certificate which was precedent to his right of action against the defendant.

This latter point arose in the case of Davis v. Taylor, in the Court of Exchequer last week. The action was by a builder, under a building contract in the ordinary form, against the architect. The declaration alleged that the defendant knew that the plaintiff had properly completed the work, and that, without reasonable cause, and fraudulently and maliciously, and to injure the plaintiff, he withheld his certificate, whereby the plaintiff was unable to obtain payment from the landowner. There was a demurrer to the declaration, and the Court have reserved their judgment. Clarke v. Watson shows that if the architect, in such cases as these, chooses to withhold his certificate, however improperly, the builder is entirely without remedy against the landowner, as he has not got the certificate, and it has hitherto been the general opinion that no action could be maintained by the builder against the architect, who is under no duty towards the builder either by contract or otherwise.

It would seem from a dictum of Willes, J., in Clarke v. Watson, that if the architect refused to exercise his judgment, and declined to consider the matter at all, the proper course for the builder would be to call upon the landowner to appoint some other architect to act in the matter. If the landowner refused to do so, it is possible that the builder might have a remedy, as the landowner might then be considered as being in the position of a person who had never appointed an architect, and had thereby himself rendered the performance of the condition precedent impossible. If the landowner by any act of

Digitized by Google

his own, prevents the builder from getting the certificate, the absence of the certificate cannot be raised by the landowner as a defence to an action by the builder. It has been decided (Batterbury v. Vyse, builder. It has been decided (batteroury v. vyso, 11 W. R. 891) that if the architect refuses to give the certificate in collusion with the landowner, the builder is relieved from the necessity of obtaining it, and can maintain an action for payment without

It does not often happen, however, that an archi-It does not often happen, however, that an architect refuses to come to an opinion on the subject of the works under his charge, or that a landowner can be proved to have caused his architect to refuse a certificate, or that it can be shown that an architect has arted maliciously in refusing a certificate. The ordinary case is (and it is one that frequently happens) that the architect, whether rightly or wrongly, has himself formed an opinion that the works are not properly done. The correctness of this opinion cannot in these cases be subjected to any test, as the builder has beforehand engaged that his test, as the builder has beforehand engaged that his payment shall depend upon the contingency of get-ting his certificate.

So far we have only dealt with the builder's rights so far we have only deart with the outlet's light at law, but in equity he is in no better position. In Bliss v. Smith (34 Beav. 508) it was held that a builder had no remedy against a landowner whose architect refused to give a certificate, unless there was either fraud or the accounts were too complicated. was either fraud or the accounts were too complicated to be taken at law. Practically, the builder's position is the same in equity as at law. The builder under an ordinary building contract is, therefore, entirely at the mercy of the architect, who is a judge from whose decision there is no appeal.

The chief objection to such a state of things depends not so much upon the fact that the builder must submit to the decision of the architect, because that is nothing more than is voluntarily accepted by every litinant who consents to an arbitration. The

must subinit to the decision of the architect, occasion that is nothing more than is voluntarily accepted by every litigant who consents to an arbitration. The real hardship is that the arbitrator is the architect, who is employed and paid solely by the landowner, and thus there may be a direct clash between the claims of the builder and the interests of the architect's employer. The architect is thus placed in a position which no one should occupy. It resembles somewhat the case of a man who is judge in his own case. Such a position renders it possible for an unscrupulous architect to do great injustice, and at the same time, makes it difficult for one who is scrupulous to do his employer justice, and it ought, therefore, to be avoided. We do not for a moment mean to say that architects placed in this position do not generally do their duty and do it well. On the contrary, we believe that in the majority of cases they strive to do justice to both parties; but notwithstanding this, they are necessarily open to suspicion on account of their position, which in itself is far more difficult than that of an ordinary arbitrator who is equally

their position, which in itself is far more difficult than that of an ordinary arbitrator who is equally independent of both parties.

The simplest remedy for this evil would be to appoint some independent person, who should, in case of dispute, be the ultimate arbitrator between the builder and the landowner. It would be easy to adopt a form of contract which should contain such a provision, and if builders were once thoroughly aware of the legal construction of their ordinary contracts, it is probable that they would, in their own defence, insist upon the insertion of some such provision as we have suggested. In the meantime, provision as we have suggested. In the meantime, some good may be done by pointing out the objections that there are to the common form of building contracts which is now generally in use.—"Solicitors' Journal."

#### THE PACIFIC RAILWAY.

THE Government of the United States appointed a Commission to examine and report upon the Pacific Railway. The Commissioners have lately issued their report, which states that with the completion of certain works yet requisite to supply deficiencies, and which are estimated to cost about £2,500,000 sterling, the road may be accepted as a first-class one, according to the understood meaning of the law passed for its construction. It will be remembered that this line was constructed with great rapidity, and it appears that this haste has been followed by a great want of care in attending to the various points connected with the proper location of the line, especially in the part across the Sierra Nevada. The curves are said to be excessive and needlessly sharp, and descents are multiplied over and over again without necessity. Gradients of 70ft, to 80ft, per mile are often introduced, where one of 53ft, per mile would have been ample, and gradients of 53ft, per mile where not more than half that rate of ascent was required. In the Humbol t valley, between Humbol t lakean: Humbolat Well, the difference of elevation is 1,111ft.; and in overcoming this tie ascents and descents amount to 6,232ft., involving, in a distance of 290 miles of road in this most practicable valley, a loss of elevation greater

trains to be hauled up an aggregate of ascents more than equal to that on the principal lines between the eastern coast of the Ohio River Valley. These are all matters which, by a little care and consideration, might easily have been avoided.

#### FOREIGN COAL AND IRON.

M. DE DORLODOT FRERES, of Acoz, have concluded a contract for 10000 concluded a contract for 10,000 tons of rails on Russian account; this contract has been nego-tiated through M. Armand Bouquié, of St. Peters-The Charleroi Chamber of Commerce has just issued a report on the metallurgical production It appears that the of that district during 1868. value of the pig and castings made in the group in 1868 was £1,171,636, as compared with £914,754 in 1867, and £1,048,950 in 1866. Iron was made in the same group last year to the value of £1,437,978 as compared with £1,368,812 in 1867, and £1,724,108 in 1866. Small current orders for iron of every description continue to reach the Belgian works, and prices are maintained with firmness in all the groups, as well for plate as for merchants' iron. The demand for iron conas for merchants from. The demand for iron continues active in the Haute-Marne; rolled iron from mixed pig has made £9 to £9 8s. per ton, while rolled iron from coke-made pig has realized £8 4s. to £8 8s. per ton. Iron has been in active demand in the Ardennes, and at Paris the advance in prices has become more and more deviced. prices has become more and more decided, both as regards iron for building purposes and coke made merchant's iron. There is not much change to report in the Belgian coal trade; at some workings there has been, however, a certain amount of activity, as it has been deemed advisable to expedite deliveries in consequence of the approaching closing of navigation.

#### SIZE FOR DRESSING COTTON YARNS.

N the process of sizeing and dressing cotton yarns or cotton warps it has been customary to a size composed of flour, china clay, tallow, and oil with an alkaline substance. An invention, however, which has recently been patented by Mr. P. M. Crane, of Manchester, oil manufacturer, consists in the employment of paraffin as a constituent in the formation of sizeing and dressing compounds for cotton materials. This substance may be added to any of the usual sizeing compounds with the most beneficial results. We give the following composition as an example of a size which Mr. Crane has found to answer well:—Flour, 280lb., or one sack; tallow, Ilb.; paraffin from 1 per cent. to 2 per cent. of the flour employed. Another useful combination consists of—Flour, 280lb., or one sack; paraffin, from 5 to 10 per cent. of the flour employed. The paraffin can be thus made to take the place of the whole or a portion of the tallow usually employed. Sometimes, in addition to the above, Mr. Crane employs a small amount of alkali. These proportions will do for the usual purposes of sizeing, but if it is desired to give the cloth more body, or to make it stiffer, a much larger proportion of paraflin may be used. The materials are intimately mixed with water, and incorporated by heat so as to form the size.

#### COAL AND IRON IN THE UNITED STATES.

THE quantity of iron made with bituminous coal in Pennsylvania in 1868 was 194,000 tons (in round figures), as compared with 191,072 tons in 1867. The production of iron made with anthracite coal in Pennsylvania last year amounted to 671,955 tons, as compared with 594,270 tons in 1867. The production of anthracite iron effected last year in Pennsylvania involved the consumption of 1,512,000 tons of coal. The production of rolled from in Pennsylvania last year is computed to have been 520,000 tons, as compared with 490,081 tons in 1867. Railway iron figured in the total for 1868 to the extent of 276,500 tons, and in that of 1867 to the extent of 245,081 tons. In 1868 the rolling mills of Pennsylvania consumed 1,210,000 tons of coal, of which 380,000 tons were anthracite, and the remainder bituminous. It is curious to observe that, notwithstanding the great increase in the demand for railway iron in the United States since the close of the war, the native production does not appear to have been very materially extended. In fact, old iron rails have been shipped to a rather considerable extent of late from

5,727 tons, while 20 small cargoes, representing 3,394 tons, were also received at Baltimore via New York. The engineers of the Grand Trunk Railway of Canada, in a report to the directors, state that rails lately re-rolled in the United States and at Toronto have proved superior to new rails imported from England. It is proposed to build an imported from England. It is proposed to build an iron bridge on the Wisconsin division of the Chicago and North-Western Railway, over the Fox River, at Oshkosh. The track on the Iowa division is being relaid with new rails of the American fish-plate pattern; the new rails are already laid for a distance of about 15 miles. The quantity of pig made in Pennsylvania in 1868 was 925,000 tons; of this total, 672,000 tons, or about 73 per cent. of the whole, was made with anthracite

NEW TYPE-SETTING AND DISTRIBUTING

NEW TYPE-SETTING AND DISTRIBUTING MACHINE.

MR. M. UMSTADTER, of Norfolk, Va., has completed a machine which he states will justify ten thousand characters per hour, the work being done with far greater exactness than can be found in any printed book. The Norfolk "Virginian," in speaking of this invention, says respecting it:—Other machines have been invented and put in operation, but the trouble with all has been the want of any appliance for "justifying," or making the lines the same length, with due regard for the space between words and the proper division upon syllables. This has, in every instance heretofore, been done by hand, and thus, as labour-saving implements, the previous inventions have been of little value. To obviate this difficulty has been the chief care of the inventor in this instance, and he claims that his machine will set and "justify" as many types in a given space of time as six men. The justification is effected by a space of his own invention, of this shape X. formed of brass or steel strips riveted together in the middle, and capable of being compressed into one-half of the ordinary thickness. The machine proper is 2ft. wide and 30 in. long, divided into as many compartments as there are different types; into these compartments the types are placed in the proper position, filling the chember, into which they fit loosely, their own weight keeping them pressed down to the bottom. In front of the machine is a double row of iron keys, lettered to correspond with the chambers of type. By pressing upon one of these keys, a type is forced from the bottom of one of the chambers into an iron trough, fitted to the exact thickness of the size of type used, so that, when once in the trough or slide, it is impossible for it to fall over on its side. Underneath this itted to the exact thickness of the size of type used, so that, when once in the trough or slide, it is impossible for it to fall over on its side. Underneath this trough runs a belt, furnished with steel hooks or teeth, and driven by a treadle beneath. These hooks convey the type along the trough to an apparatus at the end of the machine, where they are placed in regular order until a line is full, when the striking of a bull appropriate the fearth of the constitution of the bull appropriate the fearth of the constitution. placed in regular order until a line is full, when the striking of a bell announces the fact to the operator, who, by simply pulling a small lever, places the line in an upright position on a frame. The machine can be seen at David Morris' establishment, in Union-street, where he is busily engaged upon an autematic distributing apparatus to be attached to the most him, when it will be the most perfect inventor. the machine, when it will be the most perfect inven-tion for the purpose yet brought before the public. The sample of the work sent to us is very good, but no better than what has been done by other machines for the same purpose.

#### TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 ls. 8d. yearly, or 10s. 10d. half-yearly payable in

advance.
All literary communications should be addressed to the Editor of the MECHANICS MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS MAGAZINE Office, 166, Fleet-street, London.
To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.
We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.
Advertisements are inserted in the MECHANICS MAGAZINE, at the rate of 6d, per line, or 5d, per line for 13 inser-

ZINE, at the rate of 6d, per line, or 5d, per line for 13 insertions, or 4d, per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertise-

ments.

J. HOUGHTON, Wigan.—The price of the treatise for which you inquire is 10s. 6.1., by post 11s., and is sold by Messrs. Spon, of 48, Charing-cross.

A. B.—The only article which has of late appeared in the MECHANICS MAGAZINE, bearing upon the subject of your letter, is one on "Cleaning the Exterior of Houses," in our issue of April 16 last. We aivise you to apply to Messrs. Ransome and Co., of 2, Queen's-place, Southwark Bridge; they have a method of preserving stone, &c., and might assist you.

ARTHICIAL FUEL—If any 'f our readers can oblige us with the address of a maker of apparatus for the manufacture of artificial fuel by pressure, they will confer a favour.

## Meetings for the Meck.

FRI.—Royal United Service Institution.—Captain H. M. Hozier, 3rd Dragoon Guards, Topographical Staff, on "The Abyssinian Campaign," at 3 p.m.

# Habal, Military, and Gunnery Items.

THE following notification has been issued from the Admiralty:—The Bermuda dock, towed and accompanied by a squadron of Her Majesty's ships, will leave Sheerness about the 20th inst., for Madeira and Bermuda. All vessels approaching the flotilla should be prepared to take precautions to avoid the risk of collision.

Last week the Master and Brethren of the London Trinity-house laid the foundation stone of a new lighthouse to be erected on Souter Point, a headland on the Durham coast, between the Wear and Tyne. It will be erected to prevent wrecks from occurring if possible on Whitburn Steel, of which there have been so many complaints within recent years.

ADMIRAL LORD NELSON'S famous Trafalgar flag-ship, the "Victory," is to be maintained en permanence at Portsmouth, the Admiralty having issued orders that men from each of the light infantry divisions of the Royal Marine Light Infantry, together with a proportion of gunners from the Royal Marine Artillery, shall be selected for service on board the ship.

We understand that Mr. Romaine, the Second Secretary to the Admiralty, has accepted the appointment of Judge Advocate-General in India, offered to him recently by the Duke of Argyll. Mr. Romaine was Deputy Judge-Advocate in the Crimea, and at the end of the War was appointed Second Secretary to the Admiralty by Sir Charles Wood.

In the year 1868 sums amounting to £27,672 were received by the Board of Trade from masters of vessels, collectors of customs in the colonies, and consuls abroad, for wages and effects of 4.872 deceased seamen. Sums amounting to £20,444 were paid in 1868 to the relatives and representatives of of 2.685 deceased seamen. After seven years, sums unclaimed are paid into Her Majesty's Exchequer.

THE "Inconstant," the pioneer of the new type of unarmoured iron-built flying ocean cruisers, introduced into Her Majesty's Navy by the present Chief Constructor, of 4.066 tons, 1,000-horse power (nominal), to carry ten 12-ton and six 6½-ton rifled guns, has completed her armament in the steam basin of Portsmouth Dockyard, and is to have all her internal fittings completed in readiness for her measured mile trial of speed by the 29th inst.

At the close of the last Savings Banks year, on November 20, 1868, the account of deposits received by the Board of Trade under the Seamen's Savings Bank Act of 1856 showed £52,997 due to 1,662 depositors. In the year 1868, 54,121 seamen's money orders for £271,897 were issued at ports in the United Kingdom, and 1,882 orders for £22,125 at continental ports. Since May, 1855, and down to the end of 1868, 450,486 seamen's money orders for £2,807,808 have been issued at home and continental ports.

The preparations in progress at the Naval Observatory and in the Navy Department at Washington, for the observation of the total eclipse of the sun of August next, are on a very extensive scale. Two parties will be sent out to Des Moines, lowa. They will be furnished with an outfit equal to any yet supplied by any government for a similar purpose. The most skillful party of photographers at the command of the Department will accompany the expedition. A party in charge of Professor Asaph Hall, of the Observatory, and Professor Joseph Rogers, assistant, will sail in a few days for San Francisco, with a very complete outfit. On arrival in California, a war verseel will be put at their control, with orders to take the party to such place on the coast of Alaska or Siberia as may be selected.

The strength of the mercantile marine force in

or Siberia as may be selected.

The strength of the mercantile marine force in 1867 amounted to 196,340, and the number of deaths reported during that year was 5,283, yielding a proportionate mortality of 26.9 per 1,000 strength. The deaths from different diseases show that there were 367 from typhus, 214 from dysentery, 212 from cholera, 346 from yellow fever, 52 from purpura and scurvy, 151 from consumption, 1,808 by shipwreek, and 1,105 by other accidental drowning. Of the 5,233 deaths nearly half (2,442) occurred in the period of life 20-30 years. The number of deaths under 20 years of age was 932, at ages 31-40 the number was 799, at 41-50 it was 353, and at 51 years of age and upwards it was 106. The rating returns show that 2,015 of the deaths were those of able seamen, 612 were ordinary seamen, 434 mates, 433 apprentices and boys, 160 boatswains, 207 stewards, 153 cooks, 170 carpenters, 117 firemen, and 64

THE Registrar-General states—according to the returns received from his Royal Highness the General Commanding-in-Chief—that the strength of the army, at home and abroad, in the year 1867, was 200,335,—viz., at home, 87,607; abroad, 112,728. In England and the Channel Islands the strength was 60,344; in Scotland, 3,517; and in Ireland, 23,746. In the total strength at home the deaths were—of officers 49, of non-commissioned officers and men 901, representing a mortality in the former of 10-95 per 1,000, and in the latter of 10-84 per 1,000. In Great Britain the death-rate of officers was 12-55, in Ireland 6-62 per 1,000. In Great Britain the death-rate of men was 12-06, in Ireland 7-54. In the total strength abroad, in 1867, the deaths were—of officers 81, of men 2,203, representing a mortality of 13-33 per 1,000 in officers, and 20-66 in men. In 1865 the mortality of men abroad was 21-02; in 1866 it fell as low as 15-49 per 1,000.

it fell as low as 15-49 per 1,000.

The fellowing are the particulars of the Russian fleet, as given in the "Journal of St. Petersburg," from the report of the Ministry of the Marine:—On the 1st of January, 1869, the fleet counted 230 steamers and 37 sailing vessels. The former consisted of the following armour-plated vessels:—4 frigates, 3 batteries, and 13 monitors. Non-plated vessels—6 ships of the line, 8 frigates, 18 corvettes, 7 clippers, 62 gunboats, 6 vessels called "vapeurs-frigates," 4 imperial yachts, 13 schooners, 22 transports, 48 dispatch boats, and 16 chaloupes. The sailing vessels consisted of 5 yachts, 4 schooners, 15 transports, and 13 chaloupes. Of these, 156 vessels were in the Baltic, 1 in the White Sea, 30 in the Caspian, 41 in the Black Sea, 31 on the Eastern coasts of Siberia, and 22 in the sea of Ural. There were, in addition, 4 plated frigates and a steam yacht on the stocks in the Baltic, and 2 gunboats on the Siberian coast.

# Miscellanen.

THE annual conversazione of the Royal Institute of British Architects will take place at the rooms of the Institute, 9, Conduit-street, Hanover-square, on the evening of Thursday, July 1 next.

A FIRM in Oshkosh, Wisconsin, has contracted to make 1,000,000ft. of wooden tubes, to lay down in that city for gas pipes. They are made of timber 6in. square, bored in the same way as pump barrels.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending June 12, was 3,130. Total number since the opening of the Museum, free daily (May 12, 1858), 1,581,866.

Mr. T. Brassey has just completed his tour of inspection over the projected new railway from Innspruck, via Feldkirch, to the Bodensee, and his opinion seems to incline in favour of the improved Fell's system over the Arl Mountain, instead of tunnelling through it.

The "Portland (Maine) Advertiser" was recently printed on paper made of a kind of material said to have been never before used in the manufacture of paper—Zizania aquatica, or water rice. It grows in great abundance in many places in the northwest of America.

New York is suffering from a peculiar strike. The hotel waiters, who, like every other branch of working people, have a trade union, on June 1 demanded an increase of pay from thirty dollars a month, which they then got, to thirty-five dollars. It was refused, and they struck.

WITH a view of preserving the relic of Roman London—known as "London Stone"—from any further injury, the London and Middlesex Archeological Society, in conjunction with the churchwardens of St. Swithiu's Church, Cannon-street, have had placed over the casing stone a neat iron scroll guard. It is also their intention to have fixed a tablet as a memento of its origin.

THE number of visitors to the South Kensington Museum during the week ending June 12, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 10,185; Meyrick and other galleries, 1,761; on Wednesday, Thursday and Friday (admission 6d.), from 10 a.m. till 6 p.m., 2,839; Meyrick and other galleries, 228; total, 15,018. Average of corresponding week in former years, 10,268. Total from opening of Museum, 8,518,265.

A LETTER was recently read in the Legislative Assembly of Victoria, written by Mr. Robertson, of Colac, stating that between April, 1868, and the end of that year, he had a hundred men engaged on his run killing rabbits, and about 2,000,000 were killed, at a cost of £5,000. This year he has sixty men engaged on this work. It is thought likely that the impossibility of extirpating the pest on large runs will hasten the division of the land into small farms, and thus the acclimatized rabbit may exert an influence as an agrarian reformer.

NEAR Peruwels, on the Belgium frontier, a man recently presented himself early in the morning with two large elms on a timber truck, drawn by three

horses. Something about the trees attracted the attention of one of the Custom House officers, and he proceeded to examine them. He found that they had been cut open, hollowed out, and very carefully put together again, the bark, where removed, having been glued on. In the cavity thus formed, 627 kilos of tobacco were concealed. The man was taken into custody, and all the property seized.

THE Committee of the Palestine Exploration Fund have opened at the Dudley Gallery an exhibition of pottery, glass, and jewellery, the results for the most part of recent excavations at Jerusalem. In many respects the display is exceedingly interesting, especially the pottery and the lamps. A great many of the most remarkable objects come from Mount Olivet and Mount Sion. Among the jewellery are some specimens of work in silver. There is a well executed model of Jerusalem, lent by Colonel Sir H. James, and a very good collection of photographs of the Holy Land.

graphs of the Holy Land.

THE Council of the Society of Arts have this year awarded the Albert gold medal to Baron Justus von Liebig, associate of the Institute of France, foreign member of the Royal Society, Chevalier of the Legion of Honour, &c., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food-economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by arts, manufactures, and commerce." This medal was instituted to reward distinguished merit in promoting arts, manufactures, or commerce.

FROM the report of Mr. Wyndham, Secretary of Legation in Belgium, it appears that in the first five months of 1868, 22,819 head of cattle were axported from that country. This was a large increase on the exports during the same periods in 1867 and 1866, 19,971 head of the exports were sent to France. The export of sheep from Belgium to other countries was also on the increase. Butter forms a large staple of the trade between Belgium and England; the amount exported in the first five weeks of 1868 to England was 4,000,000lb. Rabbits, poultry, and game are sent almost exclusively to England.

England.

The whole quantity of land which has been enclosed in England and Wales, or is in the process of being enclosed, since the passing of the Enclosure Act of 1845, is 614.804 acres; to be reserved for exercise and recreation, 1,742 acres; to be reserved for labouring poor, 2,223 acres. It may safely be assumed that not more than three-fifths of the 614.804 acres (or 368,000) are lands waste of a manor, or subject to rights, as defined in secs. 80 and 31 of 8 and 9 Vict., cap. 118, and upon which alone, therefore, under that act, allotments for exercise and recreation, or for labouring poor, could be required by the Enclosure Commissioners.

The Chemical Society wishing to de honour to

THE Chemical Society, wishing to do honour to the memory of its late distinguished Fellow, Professor Faraday, and at the same time to promote the personal intercourse of the society with eminent foreign chemists, has recently instituted a Faraday Medal, to be awarded from time to time to some foreign chemists upon his accepting the invitation of the president and council of the society to deliver a lecture to the Fellows. The inaugural lecture will be delivered on the 17th of June, by M. Dumas, Master of the French Mint, and perpetual Secretary of the Imperial Academy, who was one of Faraday's intimate friends. By permission of the managers, the lecture will be given in the theatre of the Faraday's own expositions.

The Madras Railway Company have received advices of the opening of their North-west line to Gooty, on the 11th ultimo, for the running of trains with materials. This extension of thirty-one miles will be open for public traffice from the 1st proximo. The length of this line from Madras is thereby increased to 258 miles, and the important town and district of Gooty, with the adjoining cotton-fields of Bellary, Adonie, and Kurnool, are brought into railway communication with the presidency, and a shipping port for their produce. The construction of the branch line to Bellary, and the continuation of the main line to Raichore, the point of junction with the Great Indian Peninsular Railway, is well advanced, and will be materially promoted by the extension of the railway which has just been accomplished.

plished.

AT a general meeting of the Fellows of the Royal Botanic Society, held on Saturday, Mr. C. R. Turner in the chair, the following were proposed and elected Fellows of the society:— Messra. William Murray, Coryndon H. Luxmoor, James Vickers, John Stefanovich Schlizzi, Mrs. John Harborrow, Messrs. A. Lang Elder, W. Stafford Northcote, Lieutenant-General W. Cartwright, Miss Richards, Captain F. H. Smith, R.N., and Keith Stewart Mackenzie. The chairman of the Garden Committee called the attention of the meeting to the palm trees in flower in the open garden; they had been in their present position for about 10 years without any protection during the coldest winter. Two nearly allied species of chamerops in the Society's conservatory are also in flower.

THE meeting of the Royal Horticultural Society, held on Tuesday last, was the most attractive.

Tuesday show of the season. Among the many attractive objects perhaps Carter's double pelargona, which obtained the first prize, were the most effective. M. Baulant's artificial flowers were wonderful imitations. The lilacs were scarcely distinguishable from real specimens. The council awarded M. Baulant their Flora medal for this splendid dis-M. Baulant their Flora medal for this splendid display. Lord Londesborough presided, and the following candidates were elected Fellows of the society, viz.:—Mrs. Charles Baring, Mrs. H. R. Bran, Alfred John Cholmley, Earl Cowley, K.G., C.C.B., Hon. Mrs. Charles Eliot, Hon. R. Grosvenor, M.P., Sir Thomas Dick Lauder, Bart., William Mein, and William Smith, and the Keighley Floral and Horticultural Society was admitted into union and Horticultural Society was admitted into union.

THE receipts of cotton at the American ports showed a considerable increase in the last five weeks showed a considerable increase in the last five weeks of which we have returns, amounting, in the week ending April 30, to 22,021 bales, as compared with 18,823 bales in the corresponding week of 1868; in the week ending May 7, to 22,441 bales, as compared with 15,245 bales in the corresponding week of 1868; in the week ending May 14, to 22,207 bales, as compared with 10,707 bales in the corresponding week of 1868; in the week ending May 21, to 18,080 bales, as compared with 8,572 bales in the corresponding week of 1868; and in the week ending May 28, to 16,409 bales, as compared with 6,142 bales in the corresponding week of 1868. The aggregate receipts of the American ports to the close of May, 1869, in 1868-9 were thus increased to 2,236,217 bales, as compared with 2,237,804 bales to the close of May, 1868, in 1867-8.

RECENT communications from Adelaide. South

RECENT communications from Adelaide, South Australia, have made known the discovery. in the Australia, have made known the discovery, in the southern portion of the colony, of a remarkable carboniferous substance, which, hitherto, has only been found in small quantity in the coal strata of Derbyshire. It is a "mineral caoutchouc," so called from its general appearance and some elasticity. In Australia it is found on the surface of the sandy soil, through which it would appear to exude from beneath, as, burnt off occasionally by the bush fires, it is again found after the winter season, occurring in quantity and of various thickness. Analysis in quantity and of various thickness. Analysis proves it to contain 8.2, or more, per cent. of a pure hydro-carboniferous oil; its value for gas-producing purposes would, therefore, be great, and it is believed to be applicable to the manufacture of certain dyes. The discovery is also important from its indication of the existence of oil or other carboniferous deposits beneath the surface.

THE statistics of the book trade at Leipsic show that one-sixth of all German books is published there. The increase of the trade may be seen from the fact that in 1789, 855 works, and in 1859, 1,582 works, were sent from the Leipsic presses. Some of the Leipsic periodicals have an enormous sale. The weekly "Gartenlaube" circulates 280,000 copies. There are at present in Leipsic 47 printing establishments, which employ 1,000 men, 450 women and 300 apprentices; 100 binding shops, employing 400 binders and 160 apprentices. The music printers of Leipsic print one-third of all the music published in Germany. The book exchange at the fairs is visited by booksellers from all parts of Germany. At the Easter settling day in 1868, 3,500,000 thalers changed hands; and it is calculated that the yearly business exceeds £1,000,000 sterling. Leipsic has become such a recognized centre for bookselling that there are in it 1,282 depots of firms established in various parts of Germany. eekly "Gartenlaube" circulates There are at present in Leipsic 47

Among the most important and best "got-up" of continental scientific works, may be classed "Les Grandes Usines," by Turgan. Our present series of articles on the "Manufacture of Caps and Cart-ridges," is drawn from its valuable columns. The last three numbers contain a theoretical and practical description of the colouring of tissues, accompanied description of the colouring of tissues, accompanied by numerous cuts, diagrams, and double page illus-trations, executed in that peculiarly artistic and effective manner for which the engravings of our contemporary are remarkable. "Les Grandes Usines" has marked out a particular literary career for itself, and embraces within its sphere the description of most of the large and important manufactures and industries to be found throughout the continent. It will be within the recollection of our readers that both the establishments of M. Krupp, at Essen, and that at Creusot, were fully described in its columns. Our limits do not permit us to transcribe so much of "Los Grandes Usines" as we could wish, but we invariably exercise our privilege of selection for the benefit of our readers.

# Butents for Inbentions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system

of classification adopted, the numerical and chronologica of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclu-sively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledg-ment:—

BOILERS AND FURNACES-3691 BUILDINGS AND BUILDING MATERIALS-3642, 3650, 3668,

BUILDING AND BUILDING MATERIALS—3612, 3650, 3668, 3672, 3673, 3680

3614 J. S. TEMPLETON, Glasgow. Curpets. Dated November 27, 1868.

In Brussels and Wilton carpets, as hitherto produced, those portions of the differently coloured warps which are not brought to the upper surface by the jacquard apparatus are confined in the body of the fabric between the wefts. By the present invention they are thrown entirely or to any desired extent to the under side of the fabric, so as to form a comparatively soft coating on that side.—Patent completed.

3615 A. C. Bahlett. Thirsk. Reging and mosting.

labric, so as to ferm a comparatively soft coating on that side.—Patent completed.

3615 A. C. BAMLETT, Thirsk. Reaping and mowing.
Dated November 27, 1868.

The first part of the invention consists in the use of a sliding segment of a cam applied to that class of reaper with self delivery at the back of the machine, and which deliver a sheaf for each revolution of the reel, the object of the improved or sliding cam being to make it deliver two sheaves for each revolution of the reel. The segment of a cam is fitted loosely on the reel shaft, and can be placed in working position or withdrawn by a lever similar to a clutch lever. The second part of the invention consists in placing a small wheel on the outside shoe in advance of the kuife, which, in crossing furrows, prevents the fingers running into the ground; and the third part of the invention consists in the better lubrication of the bearing where the knife is connected to the connecting rod. That part of the connecting rod is made hollow, thereby causing it to act as an oil cup, and thus lubricating that bearing in a much better manner.—Patent completed.

pleted.

3616 T. G. Webb, Manchester. Tumblers, &c. Dated November 27, 1868.

This relates, first, to the separation of those portions of articles of glass which have been attached to the "blowing fron," which separation is usually performed with scissors while the material is in a heated state. To accomplish this the inventor uses a diamond, fixed in a suitable frame, and causes the surface of the article to move against it through the medium of a revolving table; or, by a reversed operation, he keeps the article stationary and causes the diamond to revolve. By another method, he brings the surface of the article into contact with a wire heated by electricity, The required part having been severed, he glazes the edge by causing a stream of heat to impinge upon it by means of a furnace or a blow pipe.—Patent completed.

3617 J. PETRIK, jun, Bochdale. Washing 2001. Dated

of a furnace or a blow pipe.—Patent completed.

3617 J. PETRIK, jun., Rochdale. Washing scol. Dated November 27, 1868.

This consists in effecting the object by giving motion to washors through came or wheels and connecting rods driven from the centre of motion, on which the teeth revolve bodily or within the frame which carries them. Also, in mounting the rake upon a frame, to which a reciprocating motion is imparted, but the said rake is capable of turning upon an independent centre. The material having been lifted from the trough, a series of wheels causes the said independent turning of the rake upon its centre, whereby the material is delivered at the further end of the travelling surface.—Patent abandoned 3618 T. and A. L. DICKINS and H. HEYMOOD. Middleton.

further end of the travelling surface.—Patent abandoned 3618 T. and A. L. Dickins and H. Heywood, Middleton. Washing and dyeing sitk. Dated November 27, 1868.

This consists in placing hanks of yarn upon a framework or rollers submerged in a vat, and raised upward and lowered or otherwise moved therein; and the inventors also impart rotatory motion to the said rollers while they are alternately lifted out of and plunged into the fluid, or moved to and fro therein.—Patent completed.

moved to and fro therein.—Patent completed.

3619 W. E. NEWTON, Chancery-lane. Lubricators. (A communication). Dated November 27, 1868.

This consists, first, in casing around and within the neck of a glass reservoir a metallic collar, for the purpose of connecting the reservoir to the supporting stem. Second, in combining with the collar a threaded bushing or tube of harder metal, for the reception of the stem. Third, in employing within the hollow stem of a lubricator a regulating rod, provided at its upper end with an enlargement or projection, for the purpose of supporting the rod out of contact with the journal; and, fourth, in the use, in place of the regulating rod, of a hollow tube, open at the bottom, but closed at the top, and having a hole drilled in its side near its upper end, so as to communicate with the reservoir, the tube being screwed into the hollow stem, for the purpose of facilitating the regulation of the flow of cill to the journal or bearing.—Patent completed.

3620 J. H. Dales and J. F. Maygrova, Wood-street, E.C.

3620 J. H. Dales and J. F. Maygrova, Wood-street, E.C. Looms. Dated November 27, 1868.
This relates to an improved mode of manufactaring hair, cloth, and other similar fabrics, and also to improvements

in looms used therefor. The shuttle is fed or supplied with the hairs forming the weft alternately at either side of the warp, by which means the texture of the cloth produced is rendered much more uniform than hitherto, and is otherwise improved. The hairs are much less liable to break in weaving, and the manufacture is also greatly accelerated.—Patent completed.

rated.—Patent completed.

3621 A. M. CLARK. Chancery-lane. Paper clips. (A communication). Dated November 27, 1868.

These clips are composed, first, of a plate or clip, which is pressed down by the hand and raised by the action of a spring. Second, of a hinged clip, which presses on the plate for securing the paper on slips between them, the pressure being obtained by the aid of the same spring which raises the plate after it has been depressed by the hand. The papers or slips are secured between the hinged clip and the plate. The clip is raised by the action of the plate on bearing on the latter for the purpose of inserting the paper or slip, the slip being returned to position for securing the papers by the aid of the same spring. The clip may either move in a horizontal plane or describe portion of a circle, according as it turns on an axis apprendicularly (or nearly so) with the plate, or parallel therewith.—Patent completed.

3622 W. Tranter, Birmingham. Breech-loaders and

therewith.—Patent completed.

3622 W. Tranter, Birmingham. Breech-loaders and bullets. Dated November 28, 1868.

This relates, in the first place, to a breech-loading gun with a sliding block and lock moving as required in a solid frame perpendicularly, and at right angles to the bore of the barrel, by means of the guard acting in a slot or opening made in the frame for that purpose, the solid frame formed so as to admit of the stock being made in one piece. This solid frame has a strengthening rib on each side, which fits on the top edges of the stock, the lower part of the frame passing through the stock to the under side thereof. The guard, which is in one piece, is jointed to the lower side of the frame, and acts as a lever, working in a cavity formed in the lower end of the sliding block and lock, in order to cause the said block and lock to move upwards and downwards as required.—Patent completed.

3623 J. ISCHAM and J. BUTTERFIELD, Bradford. Dressing

to move upwards and downwards as required.—Patent completed.

3623 J. Ingham and J. Butterfield, Bradford. Dressing scarps. Dated November 28, 1868.

This consists, first, in the employment of a series of brushes having bristles in two opposite sides. These brushes are caused to travel in succession upon a borizontal bed a certain distance, then to drop upon another bed parallel to the former, on which they are returned, and are then raised to the first bed again, and so on continuing to travel forward on one bed and back on the other bed. Second, in the use of a series of healds for each single end or thread of the warp to pass through, so that any of the healds may be raised or lowered so as to separate each end or thread from the others, and also open a shed or sheds for taking the "leys" required in preparing warps for the loom. Third, in the application of apparatus for stopping the action of the machine when any of the ends stick fast. The apparatus consists of a reciprocatory bar and a lever, operated by any of the healds when the ends stick together on coming in contact therewith, which lever places a stop in position for contact with the reciprocatory bar, and the bar thereby operates upon and knocks or throwsoff the strap guide.

—Patent abandoned. Patent abandoned.

3624 E. S. SAMUELL, Liverpool. Superphosphate of lime. Dated November 28, 1863. The object is to utilize those phosphatic mineral deposits recently discovered in the siturian strata of this country recently discovered in the silurian strate of this country by manufacturing them into superphosphates suitable for agricultural uses. For this purpose the inventor first re-duces the phosphatic mineral to a fine state of division or powder, and then treats it with sulphuricacid and muristic acid, or sulphuric acid and chloride of sodium.—Patent abundoned.

abundoned.

3625 A. WYLLIE and J. LATHAM, Lancaster. Cracking nuts. Dated November 28, 1868.

The inventors support on strong framework by a hinge or otherwise a serrated or rough plate, capable of being adjusted by a set screw or its equivalent to any desired angle. Opposite to the serrated or rough plate they support in a similar manner another and similar serrated or rough plate to which they give a reciprocating or vibratory motion by an eccentric or crank coupled to or connected with it. The eccentric or crank is operated by or from any convenient power. Every time, therefore, when the machine is at work the reciprocating or vibrating serrated or rough plate makes a stroke, a number of nuts are cracked. By adjusting the serrated or rough plates at the required angle to each other, nuts of different sizes can be cracked at the same time.—Patent completed.

3626 H. J. H. King, Glasgow. Gauges. Dated Novem-

3626 H. J. H. King, Glasgow. Gauges. Dated Novemer 28, 1868.

3626 H. J. B. KING, Glasgow. Gauges. Dated November 28, 1868.

This consists, principally, in providing for checking the gauges at any time by originally marking a secondary or checking scale on the dial in addition to the ordinary scale, and by fitting a hook or ring in connection with the indicating mechanism, on which hook or ring a predetermined weight may be hung. The parts may be arranged so that the added weight will act either with or against the pressure, and the checking scale is marked in accordance with the difference the weight produces in the indications when the gauge is in order. Then if the elastic element of the gauge or the indicating mechanism gets out of order and the weight be applied, the indications by the checking scale will not agree with those by the ordinary scale without the weight; whereas, if the two indications do agree upon trial, the gauge may be relied upon as being as accurate as when first made.—Patent completed.

\* 3627 J. CORNES, Ilford. Mowing graus, &c. Dated No-

vember 28, 1868.

This consists in so constructing machines employed for the above purposes as to cause them to deliver the crops behind instead of in front of the machine. To effect this the inventor makes the spiral cutter act as an elevator, and also fit an oscillating box or receptacle, or hangs the same to the back part of the machine.—Patent abandoned.

3628 A. N. Burton, High-street, Reading. Fastening boots and shoes. Dated November 28, 1868.

In manufacturing this eyelet the inventor first cuts or stamps from a sheet of thin brass, copper, or other suitable metal, a "blank" or flat piece of suitable size and shape. The portion to form the tube of the eyelet is in this case in the centre of the blank with the parts which

are to form the shank or stem projecting on opposite sides therefrom, but, if desired, the shank may be formed by a piece projecting from only one side of the tube. The shank may be formed with T-shaped projections which are inserted through a slit or aperture in the material, and then turned and clinched over the same. The shank may also be provided with claws or points, which are forced into the material, and sasist in securing the shank or may be secured by an ordinary eyclet, but it is preferred to secure the eyelet by means of a rivet or rivets passed through the shank and the leather or other material, and for this purpose he employs a pair of shoe pliers provided with a flat punch to form the slit for the insertion of the shank and a round punch for forming the rivet hole.—Patent completed.

3629 W. E. Gedge, Strand. Perspectometer. (A communication). Dated November 28, 1868.

The perspectometer, the subject of this invention, is an instrument for fixing the perspective of an object with exactness. Constructed upon rules infallible, because based upon a natural law, it always gives certain results. The perspectometer is single or double; it is divided into 100 equal parts. The double perspectometical principle that the object to be reproduced be brought beneath two lines intersecting each other at right angles. To draw with the perspectounter, whether single or double, it is necessary to retire from the object which it is desired to reproduce until it can be wholly embraced, closing one eye and keeping the arm stretched without effort.—Patent completed.

3630 W. E. Gedge, Strand. Plate warmers. (A communication.) Dated November 23, 1868.

ing the arm stretched without effort.—Patent completed. 3630 W. E. GEDGR, Strand. Plate warmers. (A communication.) Dated November 28, 1868.

This improved plate warmer is in the shape of a cylinder supported on feet, and rendered portable by handles placed at the top. In its lower part are arranged one or more sliding pans or drawers, furnished with gratings or wire gauze for the reception of any kind of fuel. This apparatus opens at the side, one part of the cylindrical casing opening on hinges for the introduction of the plates.—Patent abundoned.

cylindrical casing opening on hinges for the introduction of the plates.—Patent abandoned.

3631 C. D. Abel, Southampton-buildings. Manufacture of steel. (A communication). Dated November 28, 1868. This invention relates to the manufacture of steel by means of the new article known as "pig bloom" or "pig scrap," according to the manner in which it is produced by the process described in the specification to certain letters patent, dated November 23, 1868 (No. 3569). The inventor first makes a small amount of pig scrap, and subjects it to the process hereafter described to test the result, preparing the pig bloom or pig scrap in large quantities. Care is taken to have the oxide and cast from mixed as intimately as possible. If pig scrap is used, which is in small pieces of loose texture, it is carefully picked over, and those pieces which are seen to contain any raw cast iron being rejected, the residue when cooled is screened so as to remove any loose ore from the mass. The pieces are then placed in crucibles, and heated as a substitute for blistered steel or wrought iron in the manufacture of cast steel, the process being conducted in similar crucibles and furnaces, and in the same manner as is practised in making crucible steel, excepting that pig scrap or pig bloom broken up is used instead of blister steel or wrought iron.—Patent abandoned.

3632 J. Sarward, St. Paul-street, Islington. Preserving

wronght iron.—Patent abandoned.

3632 J. Sarward, St. Paul-street, Islington. Preserving plants, &c. Dated November 28, 1868.

The tree or plant, or flower or leaves, are taken while in a perfectly dry condition, and dipped or otherwise coated with a preservative solution in the form of an adhesive varnish of a rapidly drying nature, and not containing much water; consequently, a spirit or hydrocarbon varnish is to be preferred, and a colourless varnish of bleached shellac and spirits of wine or rectified spirits of wood; naphtha will be found to answer the purpose. By the use of such coatings, the leaf or flower is rendered impervious to the access of the air or of dampness or moisture, and thus the leaf or flower will be preserved in its natural form in a rigid or partially rigid condition.—Patent abandoned.

doned.

3633 J. L. NORTON, Belle Sauvage-yard, Ludgate hill.

Dyeing and printing. Dated November 28, 1868.

At the present time, sumach is much used in dyeing and printing in order to cause other dyes to take better on to the fabrics or fibres or materials to be dyed or printed. Now, according to this invention, an extract of the bark of the hemlock tree is substituted for the sumach, and the desired result is so obtained more effectually and economically. The extract which it is preferred to employ is that known in commerce as extract of hemlock bark.—

Patent completed.

3634 J. Heaton, Langley Mill Derby. Treating and

is that known in commerce as extract of hemlock bark.—Patent completed.

3634 J. Heaton, Langley Mill, Derby. Treating cast tron. Dated November 28, 1868.
This relates to an improved method of constructing vessels or converters in which cast iron, when in a molten state, may advantageously be subjected to the nitrate of soda, or of nitrate of potash, or of mixtures of the same, for the purpose of effecting the purification of the cast iron or the conversion of the same into steel, and consists in the employment of a fixed converting vessel, which is provided with a discharge opening at the lower portion thereof, such discharge opening at the lower portion thereof, such discharge opening being furnished with a removable plug or stopper, or with a hinged or sliding door, in order that after the purification or conversion of the cast iron the contents of the converting vessel may be readily discharged without the necessity for removing or transporting any portion of the vessel, as has hitherto been the case. The closing plug or stopper, or hinged or sliding door, may be actuated by a screw lever or other well-known mechanical contrivance in combination or not with a special catch for securing the plug or door and enabling it to support the weight of the metal above it.—Patent completed.

3635 W. NATLOR, Mildmay-park. Railway braks.

completed.

3635 W. NAYLOB, Mildmay-park. Railway braks.
Dated November 28, 1868.

This consists in a waggon framing and in a series of weighted brake levers attached to one side of or underneath each waggon or carriage, and cach weighted with a peculiar pivoted weight. It is preferred to make this pivoted weight in the form of a disc, and to pivot it eccentrically but loosely to the frame of the vehicle or to a bracket attached thereto. To a pin in the centre of this disc the upper end of a short link is connected, the lower end of which is attached to the brake lever. So long as the brake lever is elevated (the brakes being off) the pivoted weight will have its centre of gravity perpendicular over the supporting pivot, and, consequently, no

weight is given out to the brake lever, but when the brake lever is lowered for the purpose of applying the brakes, the disc revolves as an eccentric upon its pivot, and the position of its centre of gravity is changed so as to cause it to act through the link upon the brake lever, and thereby hold the brakes on. This pivoted weight is also applicable to the levers of self-acting brakes. Each brake lever is connected to a way shaft, which applies the two brakes on the same side of the waggon by the action of short lever arms and push rods. The several brake levers weighted as hereinbefore described are suspended by a rope or chain, passing under or along each vehicle over fixed grooved guide pulleys and under pulleys attached to the weighted brake levers.—Patent completed.

3636 G. S. Brown, Leicester. Communicating in trains.

the weighted brake levers.—Patent completed.

3636 G. S. Brown, Leicester. Communicating in trains.

Dated November 28, 1868.

Each carriage carries a cord or other suitable communicator which is capable of being fixed at each end to the ends of a similar cord or communicator carried by the adjoining carriages, the last carriage at each end of a train having its cord or communicator connected to signal apparatus carried by the engine or guard's van. This apparatus consists of a spring catch, which, when in one position, is capable of holding a lever carrying a bell or a hammer to strike a bell, and when operated by the cord or other communicator is released from the lever or hammer, and thereby causes the bell to sound. The bell or hammer is acted upon by a spring which, when relossed by the spring catch, causes a sudden motion of the lever or hammer away from such catch.—Patent abandoned.

3637 W. SORER, Frier-street, Reading. Brech-loading

or hammer is acted upon by a spring which, when released by the spring catch, causes a sudden motion of the lever or hammer away from such catch.—Patent abandoned.

3637 W. Sofer, Friar-street, Reading. Breech-loading frearms. Dated November 30, 1688.

This consists chiefly in the peculiar combination of parts whereby the opening of the breech, the cocking of the piece, and the extraction of the empty cartridge shell, are simultaneously effected by one movement of the hand without changing the position in which the piece is held when being fixed. The breech is closed by a block which is hinged or pivoted at one side of the rear of the barrel, and which is raised and turned laterally on its pivot to open the breech. The block is perforated centrally to receive the firing pin, which extends through the block with its ends in the proper position for receiving the blow of the cock or hammer and transmitting the same to the cartridge. The cask is arranged in combination with a tumbler and lever in such a manner that the tumbler and lever always move together, while the cock, which is drawn back by the tumbler in cocking the piece, will remain in that position when the tumbler is moved in the opposite direction. This capability of disengagement from the cock or hammer is necessary to allow the breech may be opened and the cock or hammer thrown back to full or half cock simultaneously, and that the breech may be then closed without moving the cock. The hammer is acted upon by an ordinary bent or V-shaped mainspring connected to the hammer by a swivel. The extractor is provided with a hook or claw, which is formed and arranged to catch under the rim of the cartridge in the charge chamber. The extractor is attached to a bar which is fitted to slide longitudinally at the bottom of the breech chamber. This bar through an intermediate lover is connected with the hammer, and is operated thereby in the proper direction when the hammer is cocked and released. The trigger is arranged below the stock in the ordinary maner, and

of upon a separate tumbler.—Patent completed,

3638 L. PPEIPER, Walbrook-buildings. Fastenings for
bags, &c. (A communication). Dated November 30, 1868.

In the interior of a casing, attached to one side of the
frame of a bag or other similar article, are placed two
metal sildes, each having an angular end, where they meet
in the centre of the casing, which are pressed together by
means of springs. At the back of each of these sildes is
fixed a projection, having attached thereto a pin, and in
the casing are fixed two pins running at right angles to the
former. The springs are placed on the pins which are
fixed to the projections and slides, and when a knob or stud
which projects through the exterior of the framing of the
bag is pressed upon the angular ends of the slides, they
are forced apart, and the springs are pressed against the
pins fitted in the casing, but immediately the knob is released of the pressure, the reaction of the springs force
back the slides to their former positions.—Patent completed.

back the slides to their former positions.—Patent completed.

3639 J. S. FORBES, Stoke-upon-Trent. Manufacture of carthenware, china, &c. Dated November 30, 1863.

The materials required to be calcined are operated upon in a heating chamber, with a furnace at the front end, and a wall with an outlet for a chimney flue at the back. Flues are arranged so that when the furnace is lighted, the flames are carried along parallel flues under the floor of the kiln, and up side chambers into the interior of the same, by which the heating chamber is brought to a red heat. A charge of material is then calcinod and withdrawn, and a fresh charge introduced without the heat of the furnace being materially reduced. A drying room is constructed adjoining the kiln, the flues from which are connected with other flues under the floor of the drying room, thereby drying the material as required, without the aid of another furnace. The next process is to grind the materials after they have been roughly crushed by a stone breaking machine. The material having been roughly broken, is delivered by a hopper to crushing rollers, whence it is discharged into a chamber, placed over or adjoining a hopper, to feed a pair of French buhr or other suitable stones, whence after being ground it falls into a hopper, and is delivered to another pair of grinding stones, from which it passes into a closed chamber or washtub partly filled with water.—Patent abandoned.

3640 F. Hill, Euston-road. Organs. Dated Novem

filled with water.—Patent abandoned.

3640 F. Hill, Euston-road. Organs. Dated Novem ber 30, 1868.

The chamber containing the air in a state of compression communicates with the upper channel. When the valve or pallet actuated by the pressure on the key is depressed by the connection of a wire beneath it, the air enters the organ pipe. Below the pallet, and also attached to the wire, a valve is placed and surrounded by an airtight fexible leather casing, so that the pallet and lower valve move in the same direction by mutual action, whereby the pressure of the air on the pallet will be neutralized by the corresponding pressure on the lower valve.—Patent abandoned.

3641 B. A. Green Stread. Organization alote includes

3641 R. A. Green, Strand. Ornamenting plate, jewellery, &c. Dated November 30, 1868.

This relates to improvements in the method of orna-

menting various articles of jewellery, by the application thereto of raised or convex devices or designs in gold, silver, platinum, aluminium or its alloys, or other metal produced by the electrotype process.—Patent abandoned.

3642 A. M. CLARK, Chancery-lane. Tiles. (A communication). Dated November 39, 1868.

The invention consists in the application for roofing purposes of tiles made of ordinary cast iron, the form and dimensions being varied to suit all purposes, and of a more or less ornamental appearance as desired.—Patent completed.

more or less ornamental appearance as deaired.—Patent completed.

3643 D. Greig and J. Fernie, Leeds. Plough heads, sthesis, &c. Dated November 30, 1868.

This consists in casting steel plough heads in a metal mould, by which means much labour is saved in the production of such plough heads, and one mould will serve for the casting of an indefinite number of heads. The metal moulds or chills which are used for this purpose may be cast from models made in the ordinary way, or they may be east from moulds made in plaster, and they are preferred in steel, and they may be made to stand on the floor when fixed up ready for casting, but it is preferred to fix them with hinges to a frame, so that when the castings are made, the parts of the chill may awing open, and the casting be quickly extracted at the parts where the fluid steel first touches the chill; in some cases, a recess is made, into which loam is inserted to prevent the chill being cut away by the action of the steel. In these places, when possible, it is preferred to let the steel ascend into the chill from the bottom or sides instead of falling into it. The interior of the chills is coated with washers composed of clay, ground powdered blacklead, or they are smoked in the ordinary way. In some cases, it is found desirable to give a motion to the chill, to facilitate the operation of casting, and to insure a better face on the casting.—Patent completed.

3644 N. WEST and R. G. WEST, Upper Norwood. Pre-enting corrosion of rudder pins, &c. Dated November 30,

1868.

The inventors attach to the working parts, or to contiguous surfaces in metallic connection with them, blocks or pieces of zinc or other metal, electro positive to iron, but they prefer to use zinc, by means of fastenings, preferably of iron, taking care hat a clean surface of the zinc or other metals shall be forced into intimate contact with a clean surface of the iron or steel around each fastening, and that such surfaces and the fastening itself, when of metal, shall be preserved from contact with water, whereby the corrosion of the zinc or other metal immediately around the fastening will be checked, and the block or piece will be held in place, till wholly or for the most part dissolved.—Patent completed.

3645 J. MYERS and L. L. MORRISON, Leeds. Hats. Dated November 30, 1868.

This consists in the introduction of a wire at the edge of the brim, and in curving or curling such brim in its side elevation in an elliptical manner, and, further, in causing such brim to riso towards the crown of the hat.—Patent abandoned.

elevation in an elliptical manner, and, further, in causing such brim to riso towards the crown of the hat.—Patent abandoned.

3646 W. MACLELLAN, Glasgow. Fastesiags for rails, &c. Dated November 30, 1868.

This consists in a new or improved mode and means of fastening the rails of railways, with the holding recess, and jaws formed on or in one piece, with either the chairs or the sleeper of the rails as desired, by having a wedge-shaped feather formed on the inner face of each outside jaw of the chairs or sleepers, in a position near the centre of the outer side of the holding key or wedge of the rail, so as to enter into the slit of the hollow from key formed by the two end edges of the thin flat plate, out of which the key is formed on or in its outer face, bearing on the inner surface of the outer jaw, the lower edge of the teather wedge and key having their "bevel" or wedge surfaces, corresponding and acting on each other, so that as the hollow key is driven into the recess between the jaw and the rail, the lower wedge surface of the feather acts on the edge of the key, and opens its slit, and thus (in addition to the usual tightening action of the key between the jaw and rail), by this improved construction of wedge feather and key, the lower front side and corner is adepressed, so as to tighten the opposite and corner; and also when the upper surface of the fasther is formed with a wedge "tapper" against the rail, together with the additional wedge action of the inwardly rounder surface. At the lower and upper parts of the jaw when that is desired, while to hold the key in the tightened position to which it is driven, by a hammer or mallet in the usual manner, a small projection is formed on the head or inner under edges of the wedge feather, rounded off so as to enter or "take into" any one of the set of undulatory recesses, formed along the upper surface of the key, by the elasticity due to the hollow form of the key dwhich thus prevents it from shaking back loose, by the vibration of the rails, but st

3647 J. W. REID. Paddington. Bleaching vegetable fibre.

3647 J. W. Reid. Paddington. Bleaching vegetable fibrs. Dated November 30, 1868.

The inventor applies the solution of chloride of lime to the vegetable fibre in an airtight vessel, and raises the temperature to a moderate heat, viz., from 120deg. to 180deg. Fah. The heat which he finds by practice is most effective is from 150deg. to 160deg. Fah. During the application of the heat, he prefers to agitate the material in such a way as to expose the material alternately to the action of the bleaching liquor and the gas evolved therefrom.—Patent abandoned.

abandoned.

3648 W. E. NEWTON, Chancery-lane. Cleaning cotton, &c. (A communication). Dated November 30, 1868.

This consists of a seed chamber combined with a leaf chamber, under the slotted rack, or other similar device, arranged beneath and forward of the beater, or other working cylinder, which acts upon the cotton, or other fibrous substance, as it passes between suitable feed rolls, to open the cotton and liberate the seed, leaf, and other refuse matter from the perfect fibre, and force the former through the rack or racks into the seed and leaf chambers below. The invention also consists in the use of a fender, placed so as to intervene between the seed rack and the throat or beneath the seed rack, and in contact with the lower slat thereof, so as to prevent the seeds (which have been forced through the seed rack or between the slats) from being drawn back again by the strong current of air generated by the draught fan, which draws the dust out of the machina.—Patent completed.

3649 A. V. NEWTON, Chancery-lane. Receivering mail bags, &c. (A communication). Receiving and de-lon). Dated No-

3649 A. V. NEWTON, Chancery-lane. Receiving and delivering mail bags, &c. (A communication). Dated November 30, 1868.

The object of this invention is automatically to receive and deliver in an efficient and safe manner mail bags and packages on railways into and from a carriage or carriages while in motion. To this end a scoop is arranged to swing on a vertical axis, within or through an opening made in the side of the carriage, so that when set to a working position it stands obliquely to the side thereof, and operates in connection with suitable devices for suspending the bags or packages, to be received and delivered in such manner that the receiving of the one bag or package by the interior of the scoop, catching and guiding it into the carriage, is or may be made to effect the delivery of another bag or package from the carriage. —Patent completed.

3650 A. RANSOME, Chelsea. Circular saw benches. Dated

3650 A. RANSOME, Chelsea. Circular saw benches. Dated

pactage from the carriage.—Fatent completed.

3850 A. RANSOME, Chelsea. Circular saw benches. Dated November 30, 1863

This consists in a table, on which the timber is laid, and in a circular saw, mounted as usual on a cross shaft, which at its outer end carries the driving pulleys and the grooved cone pulley, whereby motion is communicated by means of a band to the grooved cone pulley of the gearing for feeding forward the timber. This gearing consists mainly in a transverse vertical drum, around which passes one end of a rope or chain, whereby the timber is drawn forward on the table up to the saw. Within the drum ring of teeth is formed, into which gears a pinion keyed on a short longitudinal shaft. This shaft is supported in suitable bearings within the framing, and it carries a loose worm wheel, provided on one;side with clutch teeth. Into these clutch teeth the inventor takes a sliding clutch, which is carried by the short longitudinal shaft, and works over a feather on that shaft, so that it may be thrown in and out of action by means of a forked rock lever, connected by a rod with a hand lever at the opposite and feeding end of the machine. A worm on a cross shaft gears into the worm wheel on the longitudinal shaft, and upon this cross shaft is also keyed a grooved pulley with several speeds. This pulley is driven by the band from the grooved pulley on the saw shaft, which, as already explained, is the driving shaft of the machine.—Patent completed.

3651 J. H. JOHNSON, Lincoln's Inn-fields. Imitation

3651 J. H. JOHNSON, Lincoln's Inn-fields. Imitation and ivery, and stone. (A communication). Dated No.

3651 J. H. JOHNSON, Lincoln's Inn-fields. Imitation secod, torry, and stone. (A communication). Dated November 30, 1568.

This consists in grinding to a fine flock any dry fibrous material, to which flock gum shellac, or other fusible adhesive material reduced to a fine dust or powder, is to be thoroughly mixed, in the proportions of about equal parts, by weight, of each when the greatest strength is required, but these proportions may be varied for different articles, and they may be supplemented by white lead, or other substance, so as to increase or reduce the specific gravity, or by various pigments, for the purpose of colouring. A sufficient quantity of the compound or mixture for the required article is placed in a mould, the temperature of which is sufficiently elevated to fuse the gum, whereupon the said compound is subjected to pressure whilst in the mould, which pressure is maintained till the article is cold.—Patent abandoned.

3652 H. A. BONNEVILLE, Paris. Mineral teeth. (A com-

article is cold.—Tateint abandoned.

3652 H. A. Bonneville, Paris. Mineral teeth. (A communication). Dated December 1, 1868.

Each tooth is furnished with a hollow of a size exceeding that of the orifice through the teeth, by which orifice the rubber, in its plastic state, enters into the tooth, assuming, inside the internal configuration and outside, as it were, the shape of a nail head of a pyramidial form, or of the form of a flattened cone, and the rubber being properly vulcanized, the tooth becomes firmly attached to the dental piece, the hole being obtained by placing on the rear side of the tooth, which is moulded of materials well known to tooth manufacturers, a base or piece of wood, or any other material, cut into the shape of a cone, and fusible at a lower degree of temperature than that required for the tooth, the said piece of wood, or other material, being consumed or done away with during the process of biscuiting, there remains in the centre of the tooth a hollow, corresponding in size and shape with the base which has disappeared.—Patent completed.

3653 W. Betts, Wharf-road. Capsules. Dated Decem-

3653 W. BETTS, Wharf-road. Capsules. Dated Decem

3658 W. BETTS, Whati-local Copyrights in the stamping or embossing, either in relief or in intaglio, is produced on the cylindrical or conical surface of the side of the capsule. Capsules so embossed will constitute a novelty or specialty in themselves, by reason of the practical difficulties which have thinkerto stood in the way of such system of embossing.—

3654 W. BROOKES, Chancery-lane. Lace machinery A communication). Dated December 1, 1863.

3634 W. BROKES, Chancery-lane. Lace machinery.
(A communication). Dated December 1, 1868.

The object of the invention is the manufacture of fabric in lace machinery with fine muslin, or fining portions therein whilst the mesh or net portion thereof is comparatively large or coarse. For this purpose every other stump is taken out of its bar, togother with helf of the warp threads, but all the bobbin threads are kept at work as in full gauge. By these means the fabric is produced by the use of stump bars instead of by independent bars.

—Patent abandoned.

3655 J. B. SHILLCOCK, Bromley. Bottles, jars, &c. Dated December 1, 1868.

The inventor forms the necks of bottles, jars, and other similar vessels, with projections at the sides, and fits thereto an elastic band or binder of wire, or other suitable material, which turns down and passes over the cork or stopper when inserted in its place; and in the stopper, cork, or cover he also forms a groove or notch to keep the band or binder in position.—Patent abandoned.

keep the band or binder in position.—Patent abandoned, 3656 S. A. DANIELL, Birmingham. Cleaning bottles. (A communication). Dated December 1, 1868.

A horizontal axis mounted on a frame has at one end a winch by which a rotary motion may be communicated to it, and at its other end a circular disc or plate. A series of six or other number of supports for the bottles to be cleaned are fixed at equidistant points on the said disc. These supports are not fixed perpendicular to the disc, so as to lie parallel with the axis, but are so inclined that they cross the axis in directions somewhat similar to the directions of the threads of a quick-threaded screw. Each of these supports has, near its botten, a shallow conical cup in which the bottom of the bottle is supported; near the top end of sach support is a slot in which a bracket carrying a tube or hollow cylinder slides, the said brackets

being capable of being fixed at any required position by means of clamping screws.—Patent abandoned.

3657 E. PRICE, Cheapside. Shirt front and collar. Dated December 1, 18

December 1, 1868.

The laventor proposes to form the shirt front either plain or with pleats, being worn with or without studs, and with a closed front pleat or fold; the neck band is then continued beyond the limits of the collar itself, which is attached thereto in the ordinary manner. Thus the collar is connected at one end with the shirt front, and the other portion of the collar is passed round the back of the neck and brought to the front of the band, to which it is fastened by a stud in the centre of the front and a button or stud at the side or edge of the neck band.—Patent abandoned.

2658 J. H. JOHNSON Lincoln's Inpublika Comition

abandoned.

3658 J. H. JOHNSON, Lincoln's Inn-fields. Carding engines. (A communication). Dated December 1, 1868.
This consists in substituting for the annular intervals or spaces formed by bands of leather which are interposed between the rings of card in the doffing cylinder, thin metal blades having knife edges, and secured parallel to each other and side by side in a metal frame which is fixed to the main frame of the carding engine. These thin blades are disposed nearly vertically in front of the doffing cylinder, and are caused to enter the cards to a depth of about 1-16th of an inch, the length of blade in actual contact with the circumference of the doffer being about 2in. The length of the "doffer" is thus subdivided into as many spaces as may be required without the great loss of working space attendant upon the old system.—Patent completed.

or working space attendant upon the old system.—Patent completed.

3659 H. W. FULLER and J. W. BARNUM, New York, U.S.A. Swing machines. Dated December 1, 1868.

The machines constructed according to this invention have a base plate or block to be attached to the bed plate of a sewing machine in a permanent situation thereon with respect to the needle. It is usually so attached by the gauge screw of the machine. Arranged by the side of the base plate is a long plate which is termed the bed plate. This plate is firmly fastened at the back end to a short transverse plate termed a binder. In the binder is fixed a post which passes up through a slot in the base plate and carries a binding nut. In the top of the post, and made fast thereto, is a spring lever carrying one or more of the creasing devices. The devices preferred consist of jaws which pinch or nip the fabric between them, and form a crease on the under side of the fabric by creating a ridge on the top thereof. The modifications thereof consist of a notch and a point or edge arranged on opposite sides of the fabric and crease it by driving a portion thereof into the notch.—Patent completed.

3660 J. GRINDBOD, Chester. Ships. Dated December 1,

3660 J. GRINDROD, Chester. Ships. Dated December 1

1868.
This consists in taking away or opening out as much of the dead surface aft (commonly known as deadwood) as will allow the water to escape or pass through or under, instead of impinging against it, thereby insuring a quick turning of the vessel and a quick helm, and the patentee prefers that there should be little or no gripe forward, or, in other words, that the keel should run up forward.—

Betant completed. in other words, t Patent completed.

Batent completed.

3661 C. S. ROSTAING, Paris. Telegraph cables. Dated December 2, 1868.

To construct these elastic cables the inventor commences by taking a cord or rope of variable diameter, and made of semi-vulcanized india-rubber, of unalterable gutta-percha, of hemp or flax impregnated with a solution of caoutehour, or of gutta-percha, or even made of other materials more or less elastic. This cord or core must be placed in any suitable machine which will give it such a rotary motion that one or more copper wires may be wound spirally upon it. When the elastic cord or core is furnished with the spirals of copper or other metal, they are covered with thin bands or ribbons of india-rubber, or of fabrics prepared with india-rubber freed from efflorences of sulphur by passing sulphure tof carbon or other solvent over their surface, taking care to wind the first band, following the direction of the copper spirals, and that the second layer would be wound in reverse direction to the first. The object of winding the isolating and wire protecting coverings in contrary or alternate directions as above set forth, is to preserve the elasticity of every part of the cable in order that neither traction nor compression may affect any deterioration of the wire.—Patent abandoned.

3662 P. Ellis, Liverpool. Letter box. Dated Decem-1868

ber 2, 1868.

This consists of a letter box so arranged that the letters deposited therein are absolutely safe from all external attempts at abstraction, and a letter bag intended to be attached at the base of the box, so arranged that on removal from the box the opening is closed and the access to the letters by the shutter in the face only, the key of which is in the possession of the owner. The first part of the arrangement is appropriate to residences and chambers, and the whole for post-office collecting pillars, and for those who object to their correspondence passing into the hands of their servants, but receive the bag and open for themselves.—Patent completed.

are reversed, the shortening layers of steel being on the concave. It is proposed so to place these wheels that they sustain the principal part of the load.—Patent completed.

pleted.

3664 J. TIDMARSH, Twickenham. Clipping and shearing.
Dated December 2, 1868.

This consists essentially in the employment of combes, segmental in shape, with the teeth thereof close together, and not radiating from one common centre in combination with a plate, to which a to and fro motion is imparted, also segmental in shape, and carrying cutting blades or teeth (by preference, three), but which do not radiate from a common centre.—Patent completed.

3665 T. WARBURTON, Haslingden. Piecing cotton card-

3665 T. WARBURTON, Haslingden. Piecing cotton cardings. Dated December 2, 1868.

This consists in a method of piecing the cardings, whereby the occurrence of hard places at the points of piecing is prevented. The cardings, instead of being placed singly, as hitherto practised, are pieced double or in pairs (or in groups of three or more), and in such a way that the piecings of each pair of cardings overlap for about an inch. This is effected, principally, by driving the brat at half its usual speed, so that when one set of cardings has advanced about half its length, a second set is delivered from the buckets, and when the first set has advanced in full length, a third set is delivered, with is ends overlapping the first set about an inch and the second about set half way, and so on.—Patent abandoned.

3666 E. HELY, Dublin. Envelopes. Dated December 2,

3666 E. HELY, Dublin. Envelopes. Dated December 2, 1868.

This consists in arranging the various parts of the machine so that they may be made to perform their various functions without the necessity for a continuous driving motion, they being all worked from one foot lever or treadle. This treadle first brings into motion a hammer, causing it to turn over on a pivot or centre, and to emboss the design on the seal flap of the blank by the aid of a fixed die, situate under the hammer face. By this motion of the hammer two appliances may be brought down, if desired, for the purpose of pressing the requisite parts of the blank against the gumming or cementing appliances, after which they, in company with the hammer, are moved back again to their original position, and a plunger of the size of the envelope descends upon the blank and forces it down into a box, sliding like a piston in a cavity in the table of the machine, the four flaps of the envelope being left erect. The continued or further descent of the plunger forces the box still further downwards, and by the action of four folding flappers, which are hinged to the edge of the said box, and are forced inwards by contact with the outer edges of the opening in the metal table, through which the box descends, the erect flaps of the envelope are folded or turned down round or over the edges of the plunger, which completes the folding of the envelope. As the plunger ascends again with the folded envelope. As the plunger ascends as a hereinbefore described for the next envelope, and so on. The peculiar folding action of this machine leaves a thickened edge on the envelope of any desired depth or thickness.—Patent completed.

3667 J. Alexander and J. Hill, Dublin. Railsety

the envelope of any desired depth or thickness.—Patent completed.

3667 J. ALEXANDER and J. Hill, Dublin. Railsey signals. Dated December 2, 1868.

The passage of the locomotive over particular portions of the line is made the motive power for working the signals, either at the extremities of sharp curves, entrances to tunnels or stations, or even along the entire line of railway if required. The inventors arrange on either side of the rail, or of both rails, a bar of iron or steel, presenting a raised curvilinear or segmental surface above the level of the rail, such raised surface receiving contact from the flange or edge of the tyre of the wheels of the engine or train, and becoming thereby depressed to the level of the rails. The rails themselves will not therefore be interfered with, and the engine guard bars will be free to travel over the rails without touching the raised segmental bar. This bar should be from 6ft to 8ft, or thereabouts, in length, and a corresponding depth in the principle of a beam or grider, to resist a lever strain, and is attached at or near one end to a fulcrum or axis, below the level of the rails and at right angles thereto. The ends of the bar are formed with a gradual ascent, each extremity lying well below the surface of the rail, to permit the engine wheels to run smoothly thereon, and to effect a gradual depression from the fulcrum or axis, which then extends completely in a transverse direction under the rails to any extent required, to act on a vertical arm, to which is attached the chain or rope by which the signals are operated; and where required to work along the entire line, what is technically called a dog is made to work into each lever, so as to cause a continuation or succession of signals to operate, so as to affect only those required as the train passes on.—Patent completed.

3668 H. N. MAYNARD, Crumlin. Girders. Dated December 2, 1868.

3668 H. N. MAYNARD, Crumlin. Girders. Dated December 2, 1868.

of the arrangement is appropriate to residences and chambers, and the whole for post-office collecting pillars, and for those who object to their correspondence passing into the hands of their servants, but receive the bag and open for themselves.—Patent completed.

3663 P. Ellis, Liverpool. Omnibus. Dated December 2, 1863.

This consists, first, in an iron frame or carriage, strictly so called, extending from the principal wheels, and thereto secured round the front of the body, and thence projecting to and resting upon the axis of the fore wheels is by means of a vertical bar accurate into the swan neck, and extending into the socket of the axis, the socket as formed as to admit free motion in the vertical bar. Secured upon a plate are two springs, one on each side of the vertical bar. The ends of these springs are connected by appropriate couplings with the axis of the fore wheels; thus in traction no force is in operation on the springs but wholly on the vertical bar. The ends of the sax of the sum of th

3669 S. C. LISTER, Manningham. Weaving. Dated December 2, 1868.

The inventor ties in the pile loops, each with one shoot of weit only, or two may be used, but he prefers one. This enables him to use a coarser weit, and at the same time to obtain a richer pile, whilst, at the same time, by well filling the cloths with weft, as firm a tie is obtained as heretofore. Each pile warp thread may be caught into the cloths by every shoot of the weft in each cloth, but it is preferred to divide the warps into two parts, which in each cloth are caught alternately by the successive shoots of weft. In this way a more regular covering of the cloths by the pile is obtained.—Patent completed.

3670 S. PALLANT. Recent-streat. Fastenings for stars.

the cloths by the pile is obtained.—Patent completed.

3670 S. PALLANT, Regent-street. Fastenings for stays, &c. Dated December 2, 1883.

The inventor fixes on to one of the two edges to be fastened a stiffener of thin steel or other suitable material, having upon it at distances apart a number of stude or hooks, or such like appliances, and on to the other edge he attaches another stiffener, with hooks or similar fasteners upon it, which last mentioned stiffener is jointed opposite each of the hooks or fasteners which it carries, so that by bending the jointed stiffener at each of its joints in succession, each hook or fastener as brought into such a position that it can be passed behind the corresponding stud or hook or such like appliance on the other fastener, and as each joint is straightened its hook or fastener assumes such a position that it is unable to pass back from behind the stud or appliance on which it has been made to catch, and so the parts are securely connected together. At the end or ends of the stiffeners they are held together by a stud and eye, or by other convenient means, which will hold them together and prevent motion longitudinally.—Patent completed.

2671 J. B. Hubbell, Euston-square. Reflectors. (A com-

3671 J. H. HUMBELL, Euston-square. Reflectors. (A communication). Dated December 2, 1868.

This consists in a metal shield or reflector, made bright on its under side and pierced at the centre to allow of the flame of the lamp passing up through it. It is fitted to the argend or other burner, and by means of a pinion in gear with a rack connected with the reflector it is made capable of vertical ediasteron upstifucion to the thorum flame. of vertical adjustment relatively to the lamp flame.-Patent abandoned.

abandoned.

3672 P. Hooker, Old-street-road. Brickmaking. Dated December 2, 1868.

The inventor employs an ordinary punching press to mould and press the bricks, and the improvements consist in providing means for removing the mould from under the plunger of the press after it has compressed a brick within said mould, and of removing the brick therefrom. To effect this he provides a slide at one side of the machine, working in gfdes fixed on the table, and operated by a hand lever and connecting rod, by means of which the mould is moved from under the plunger of the machine to the point of delivery after the latter has compressed a brick therein.—Patent completed.

3673 A. M. CLARK, Chancery-lane. Paving blocks. (A

3673 A. M. CLARK, Chancery-lane. Paving blocks. (A communication). Dated December 2, 1868.

This comprises, first, mineralizing the wood paving blocks; second, an improved concrete; third, an improved waterproof coating; fourth, an improved adhesive mastic; fifth, an improved mineral giue; and sixth, an improved solid glue.—Patont completed.

solid glue.—Patont completed.

3674 E.W. P. TAUNTON, Birmingham. Chairs. (A communication). Dated December 2, 1868.

This consists in applying a spring to each of the front legs of chairs in the manner hereinafter explained. This spring is interposed between the bottom of the leg of the chair and the floor, whereby the front of the chair is raised. The gentle inclination of the body backwards and forwards occasions an alternate compression and relaxation of the springs, and, consequently, a rocking motion in the chair.—Patent abandoned.

in the chair.—Patent abandoned.

3675 D. Dorrity, France. Locking printers' formes.

Dated December 3, 1868.

In constructing this improved locking apparatus or mechanical furniture, the inventor provides a metal frame, by preference oblong, and he fits into its centre a vertical pinion, the teeth of which being of helical or spiral shape, he causes to gear into those of two adjacent horizontal toothed wheels or endless screws, one on each side of the pinion, and each of these gearing into another wheel or serow of the same description, and likewise furnished with teeth or threads of appropriate shape, and the whole of this gear may be mounted or fitted into the aforesaid frame or casing by means of axles, or in any other manner. The toothed wheels or endless screws being made hollow, he so fits a screw of a smaller diameter into each of them as to cause these wheels to form the nuts or female screws of the (male) screws or tapered spindles, so that each of as to cause these wheels to form the nuts or female screws of the (male) screws or tapered spindles, so that each of these will proceed out of or recede into its nut according to the direction in which the latter revolves, the two inside spindles moving in one direction whilst the two outside ones move in another. To the outer ends of every pair of spindles he fits a thin metal plate corresponding in width and shape to the outer surfaces of the frame or casing of the apparatus, so that one plate may connect the two outside and another on the opposite side of the frame the two inside spindles with each other.—Patent completed.

2676 I. J. Marguar. Bishopsgetestreet Without

completed.

3676 L. J. MARBCHAL, Bishopsgate-street Without.

Safety lock. Dated December 3, 1868.

Instead of the ordinary key, the inventor uses a special stock furnished with bits or teeth of different lengths according to the interior combinations of the lock, so as to permit of the free movement of the bolt or bolt and latch. The action of the teeth or bits by pressure places upon an equal line a series of slots cut in many movable blades in proportion to the numbers and lengths of the different bits or teeth, so as to permit of a free passage within these slots of a comb fastened on to the bolt, which comb in any other position of the blades is immovable.—Patent completed.

3677 H. W. GRYLLS. Great St. Helen's. Motive power.

3677 H. W. GRYLLS, Great St. Helen's. Motive power. Dated December 3, 1868.

Dated December 3, 1868.

The inventor makes a metal or wood frame to which he fixes a shaft, on the frame of which is fixed a cog wheel which gears with the cogwheel on the flywheel. A spring or springs is or are fixed on this latter shaft, which has also a ratchet wheel and a catch to check the action of the springs when required. He also places on this shaft one or more large wheels fastened to a disc or discs or iron plate for gearing into the wheel or wheels on the second shaft or axle for driving machinery or fans or other appliances that may require to be driven. To obtain in anchors.

great power, he uses two shafts instead of one only. He then uses large drum springs fixed on a cylinder or cylinders, on the sides of each of which he fixes a disc, and fastens the same together by bolts and nuts, and thus encloses the spring or springs; at the side of the disc is a slot to receive a sliding her attached to the spring to keep it from breaking when winding. On the side of each disc he places one or more wheels for driving as may be required, which gear with wheels on the second shaft or axle; the whole of this mechanism is fixed on the first stated shaft.—Patent abandoned.

3678 W. Pugh and J. FIELD, Bow-street. Lenses. Dated December 3, 1868

December 3, 1868.

This consists in the employment of two glasses or pebbles, one placed on the other, and secured together. Supposing a 2-inch tinted concave lens is required, a shell of tinted gluss neutral, before being cemented and ourved on one side of the lens, is taken, into which the second lens is balsamed or otherwise fixed. An equal tint is thus maintained throughout, no matter what focus may be desired.—Patent abandoned.

thus maintained throughout, no matter what focus may be desired.—Patent abandoned.

3679 W. E. Geder, Strand. Ploughs. (A communication). Dated December 3, 1868.

This consists in certain modifications of the share and mould board, in the application to the beam and combined stays, props or body, of a socket piece of turn wings, and of a share forming a Grecian plough, and to this same socket of a small share to form a grubber. The beam is of wood, with two plough handles or levers fixed by two bolts and nuts, the sole or slade, and body or stays, forming a single piece; the two props have at the top two beans, which enter the wooden beam, and are there finally fixed by two strong bolts and nuts. The sole carries a pivot front and back. The front pivot enters into a hole made under the fore part of the mould board, and a hole at the back receives the second pivot, which is at the extremity of a support or buttress having two branches. At the other end, and at the extremity of each of these branches, is a cramp iron which hooks the mould board by means of two fixed catch holes or staples. A rod held by one end fixed to a hole in the mould board, enters the hole placed in front of the spring of the branches of the buttress, and is there fixed by a nut; it is this rod which keeps the entire arrangement in position.—Patent abandoned.

3680 J. H. BANKS, Knutsford. Building. Dated Decembers 1888.

3680 J. H. BANKS, Knutsford. Building. Dated Decem-

ber 3, 1868.

By the use of iron buttress standards placed at defined distances apart, the inventor nearly relieves the walls of the weight and thrust. These standards have flanges formed upon them so arranged that the spaces between one standard and another can be filled in with boarding bricks and bond timber, rubble and bond timber, or any other material, as may be desired; also upon the upper extremity of the standards a shoe is formed to receive the end of roof principals. One side of the shoe is formed of a separate plate, which manner of construction allows the woodwork to be bolted tightly up to the side of the shoe, which is a part and parcel of the principal.—Patent abandoned.

3691 J. LITTLER and J. H. BANKS, Knutsford. Furnaces and December 3, 1868.

asal J. LITTLEE and J. H. BARKS, RIUGSTOTA. Furnaces, Dated December 3, 1868.
Ordinary furnaces consist of one chamber. By this invention, the chamber is to a certain degree partially divided, according to circumstances, in the following manner:—First, in the case of furnaces of salt pans, which are generally very broad and short, and others of similar construction and proportion (such as are used for the purpose of baking, heating, boiling, and melting, not being furnaces for the generation of steam) at any defined distance between what is commonly termed the bridge and the door, one or more partial divisions are made transversely, which divisions depend down from the upper surface of furnace to within any distance from the firebars, which may be found desirable according to the magnitude and nature of the furnace.—Patent completed.

3832 C. H. CHABBURN, Liverpool. Drawing instrument,

which may be found desirable according to the magnitude and nature of the furnace.—Patent completed.

8632 C. H. CHADBURN, Liverpool. Drawing instrument.
Dated December 3, 1868.

This instrument is called the "catholograph," and it consists of a pair of cross levers working on a fixed axis, in or near the centre of their length. The ends of these levers or beams are connected at each end by a pair of link or connecting rods, jointed together at one end, and to the extremities of the cross levers at the other, so as to form two sections, constructed on the lazy tongs principle. The axis or fixed centre upon which the cross levers work is formed with a clamp or other suitable means of attachment, for fixing the same to a drawing board, drawing block, or a frame on which the paper, canvas or other material to receive the drawing or sketch is intended, and which is placed in a vertical or nearly vertical position when the instrument is being operated with. A pencil or other tracing point is fitted to one of the connecting rods on the lower end of the cross levers, so as to be in front of the paper or other material which is to receive the drawing.—Patent completed.

3683 R. HORNSEY and J. E. PHILLIPS, Grantham. Mos-

ing.—Patent completed.

3683 R. HORNSBY and J. E. PHILLIPS, Grantham. Mousing. Dated December 3, 1868.

In reaping machines, in which the crop is delivered at the side of the platform in a continuous swathe, there is necessarily the weight of the delivering apparatus on the platform of the machine, and it is desirable to counterbalance this weight, by placing the other weights on the other side of the main carrying wheel. The inventors, therefore, mount the whole of the driving gear of such machines, so that it is carried entirely by a single frame on the outer side of the main carrying wheel. The frame is, by preference, formed of top and bottom bars of wrought iron, with cast iron distance blocks between them.—Patent completed.

#### APPLICATIONS FOR LETTERS PATENT

Dated June 8, 1869.

1765 A. Williams, Bankside, Southwark, Surrey. Improvements in gas stoves for cooking purposes.

1766 B. J. B. Mills, Southampton-buildings, Middlesex. Improvements in obtaining lithographic compositions or printing surfaces.

1767 H. Carter and G. H. Edwards, Bow, Middlesex. Improvements in breech-loading firearms known as Chassepot rifies.

1768 D. Cole, Bitterne, Southampton, Improvements in anchors.

1769 M. Michel, Edinburgh. Improvements in aerial navigation, and in apparatus employed therefor.
1770 fA. Gardiner, Manchester. Improved means of checking the receipts of omnibus guards, conductors of public vehicles, and other persons employed as money takers.

kers. 1771 W. Cubley, Newark, Nottinghamshire. Improvements in drawing boards.
1772 A. M. Clark, Chancery-lane. Improvements in machinery for propelling vessels.

machinery for propelling vessels.

Dated June 9, 1869.

1773 V. J. Four, Marseille, France. An improved case or box for containing matches or other articles.

1774 W. E. Gedge, Wellington-street, Strand. An improved machine or apparatus for treating leather to render it suitable for making straps, belts, or bands.

1775 R. Roberts, Haulgh, Little Bolton, Lancashire., Improvements in mechanical and artificial dentistry.

1776 D. J. Field, Auborn House, Ashton-on-Mersey, Chester, and I. W. Lister, Welliadd, Rochdale. Improvements in machines for compressing wool or other substances.

ments in machines for compressions.

1777 J. Mabson, Norwood, Surrey. Improvements in, and connected with, sewing machines, the production of new stitches or new work in sewing machines, and the combination with sewing machines of a certain other description of machine.

1778 A. J. Billing, White Lion-street, Chelsea, Middlesex. Improvements in roller blind furniture.

1779 W. Madders and J. Wood, Manchester. Improvements in machinery for embroidering.

1780 J.T. Twigge, Edinburgh. Improvements in velocipedes.

1781 H. W. Hammond, Manchester. Improvements in

pedes.

1781 H. W. Hammond, Manchester. Improvements in hammers for forging metals and for other purposes, and in the mode of actuating the same.

1782 A. St. C. Badisson, Lyons, France. Improvements in the treatment of oleine and other fatty matters for the purpose of transforming them into solid materials suitable for the manufacture of candles.

1783 E. Bishop, Steffield. Improvements in shears, specially applicable to those used for sheap shearing.

1784 N. R. Hall, Rusherville, Kant. Improvements in apparatus for weighing letters and other articles.

1785 W. L. Wise, Chandos Chambers, Addiphl, Westminster. Improvements in the manufacture of artiticial fuel, and in apparatus for the purpose.

1786 W. Chambers, United University Club, Middlesex. Improvements in refrigerating and ventilating carriages, trucks, or other movable or fixed apparatus used for conveying or storing animal or vegetable substances of a perishable mature.

1787 G. Johnson, Coventry, Warwickshire. Improvements in looms for weaving ribbons, trimmings, and frillings.

ments in looms for weaving months, in looms, frillings.

1788 R. Harrison, Port Madoc, Carnarvonshire. Improvements in machinery or apparatus for squaring or dressing roofing slates and counting and registering the same, and loading the slates on to waggous or trucks, part of which improvements is also applicable to sawing machines for wood.

Dated June 10, 1869.

of which improvements is also applicable to sawing machines for wood.

Dated June 10, 1869.

1789 C. Denbeigh, Ironmouger-lane, Cheapside, City, Improvements in the construction of velocipedes, and in the manner of driving and guiding them.

1790 G. Fry, Ethelburga House, Bishopsgate-street Within, Middlesex. Improvements in the treatment of wood for obtaining fibre for the manufacture of paper and cordage, also for the production of acid, spirit, ether, rosin, and other substances or liquids from wood.

1791 G. Bedeil, Liverpool. An improved apparatus for readjusting railway locomotives, carriages, and other rolling stock thrown of ithe metals of railways and tramways.

1792 J. Blair, Caledon Mills, Manchester. Improvements in the manufacture of wadding.

1793 T. Riley, Shoreditch, Middlesex. Improvements in the manufacture of wire cloth or gauze used in the manufacture of wire cloth or gauze used in the manufacture of paper and other similar purposes.

1795 T. Foster and J. Hollinrake, Bury, Lancashire. Improvements in apparatus for the prevention of emoke in furnaces.

1796 W. Cook, Aberdeen Park, Highbury, Middlesex. Improvements in apparatus for taking photographic discontinuations and the descriptions of taking photographic discontinuance of the prevention of emoke in apparatus for taking photographic discontinuance of the prevention of emoke in apparatus for taking photographic discontinuance of the prevention of the prevention of taking photographic disc

in furnaces.

1796 W. Cook, Aberdeen Park, Highbury, Middlesex. Improvements in apparatus for taking photographic pictures by which the operator can take a number of prepared sensitive plates and expose them successively without the aid of extra changing box or bag.

1797 W. R. Lake, Southampton-buildings, Chancerylane. An improved covering for floors and other surfaces.

1798 W. A. Glibee, South-street, Finsbury, Middlesex. An improved method of conveyance and transportation in pneumatic tubes.

pneumatic tubes.
1799 J. G. Marshall, Leeds. Improvements in veloci-

pedes. 1800 G. W. Oliver, Liverpool. Improvements in the manufacture of explosive powder, and in machinery to be used in such manufacture.

Dated June 11, 1869.

1801 W. A. Lyttle, The Grove, Hammersmith, Middle-ex. Improvements in electro-telegraphic apparatus.

1802 E. T. Hughes, Chancery-lane. Improvements in awa or other similar instruments for cutting and dress-

saws or other similar instantiation.

1803 A. A. Ardisson, Boulevart Magenta, Paris. An improved appearatus for stopping horses when they run away or become unmanageable.

1804 W. E. Newton, Chancery-lane. Improvements in submarine drilling appearatus.

1805 C. Stuart and W. Walker, Manchester. Improvements in apparatus for expauding the ends of boiler and other tubes, and also for plugging the same when required.

Dated June 12, 1869. 1806 J. Hill, Wolverhampton, Staffordshire. Improvements in furnaces for steam boilers and for other pur-

poses, 1807 B. Duckworth, W. Greenwood, J. Pearson, and J. Langtree, Blackburn, Lancashire. Improved apparatus or appliances to be employed for sizeing and warping yarns

and for weaving.

1803 R. Wilson, Blackburn, Lancashire. Improved fasteners for neckties.

1809 A. La argue, Park-road, Newcastle-on-Tyne. Im-

provements in apparatus for weighing and registering.

1810 J. H. Riddell, Cheapside, City. Improvements in joints or connections for uniting and securing together the ends of pipes or tubes.

1811 G. W. Howe, Regent-street. An improved construction of steam gauge.

1812 J. H. Brown, Abbey Mills, Romsey, Hants. Improvements in the manufacture of helmets, hats, caps, and similar articles, and in the apparatus and arrangement thereof.

and similar articles, and in the apparatus and arrangement thereof.

Dated June 14, 1869.

1813 C. Mather, Salford Iron Works, Manchester. Improvements in machinery for ginning, burring, and cleaning cotton and other fibrous substances.

1814 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in sewing machines, chiefly designed for sewing the outer soles to the welts of boots and shoes.

1815 L. H. Dennis, Birkenhead, Chester. An improved apparatus for cutting or dividing glass.

1816 E. G. Brewer, Chancery-lane. Improvements in connecting pipes or tubes.

1817 R. Brown, Glasgow. Improvements in the manufacture of iron.

1818 J. Taylor, Russell-street, Bermondsey-street, S.E. A floating and sliding top for wells, tanks, cisterns, or any other kind of vessel for keeping or holding water, fermented or untermented, or any other kind of liquor.

1819 W. S. Underhill, Newport, Salop, and J. Smith, Church Aston, Edgmond, Salop. Improvements in reaping and mowing machines.

1820 W. E. Newton, Chancery-lane. An improved attachment for, and mode of, actuating ships' pumps.

1821 J. Young, Houghton-le-Spring, Durham. An improvement in the silde valves of steam engines.

1822 J. G. Tongue, Southampton-buildings, Chancerylane. Improvements in shuttles for weaving.

1824 D. Fitzgerald, New York, U.S.A. Firing pro-

shoes.

1824 D. Fitzgerald, New York, U.S.A. Firing projectiles from a cannon or mortar which is attached to a vessel, and which is termed a submarine cannon or

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.O., to whom all communications upon the subject should be addressed.

SOIENCE AND ART.—A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brocches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[ADVY.]

WHEEL, RACK, and SCREW CUTTING
SPUR, BEVEL, RATCHET, WORM, and INTERNAL
wHEELS ont to any size or number of teeth alsoracks of any length
er pitch. Dividing plates drilled or linds. Screws out to any segen
pitch. J. Wilkinson, Engineer, St. George's Works, 42, late 3, 5t
George's road, S.E., London.

DINNEFORD'S FLUID MAGNESIA.—
The Medical Profession for thirty years have approved of this pure Solution of Magnesia as the best remedy for Acidity of the Stomach, Heartburn, Headache, Gout, and Indigestion: and as the best mild aperient for delicate constitutions, especially adapted for Ladles, Children, and Infants.

DINNEFORD AND Co., CHEMISTS,
173, New Bond-street, London,
And of all other chemists throughout the world.

A 5

UXURIANT WHISKERS, MOUSretired apothecary, from Wales, will send his noted FORMULA for 13 stamps and stamp-directed cavelope, to produce Hair on the Head, Whiskers and Moustaches on the Face in three weeks.—MR. EVAN EVANS, M.D., C.M., Dorking, Surrey.

STAMP DUTY OF £100
PAID.
18322H. and J. Davenport

ADIES and GENTLEMEN, having
connection, may hear of an AGENCY that will add to the
income from £3 to £5 per month. Address (enclosing saveleps), JARES JETTERSON, ESC., Forest Hill, London, S.E.

# THOMAS TURTON AND SONS,

celected from.

THE SILVERTOWN

#### LUBRICATED ELASTIC STEAM PACKING.

(Lubricated Cotton, with India-rubber Core) ELEVATION. SECTION:

This Packing is far superior to any other kind made. It is already lubricated and ready to put in its place. It lasts a much longer time than any other packing now in use, and requires oiling but once per day, thus effecting an immense saving in the cost of oil and labour.

It can be worked either with or without oil or grease; but it is recommended to lubricate it once per day, which will keep the gland perfectly steam-tight, and the rod bright and clean.

Price 2s. 6d. per lb.

Made in lengths of 20 feet and upwards.
HE INDIA RUBBER, GUTTA PERCHA,
AND TELEGRAPH WORKS COMPANY,
LIMITED.

Works:—SILVERTOWN, ESSEX. WAREHOUSE: -100, CANNON STREET, LONDON.

Notice.-All Orders should be ad

to the Works.

THE

#### MECHANICS' MAGAZINE.

LONDON: FRIDAY, JUNE 25, 1869,

#### THE PROPOSED FARADAY MEMORIAL.

THE proposition to provide a public memorial to the memory of the late Pro-fessor Faraday, assumed a practical form on Monday last, when a meeting was held at the Royal Institution, at which the Prince of Wales presided; the object being to promote the matter in question. There was a goodly the matter in question. There was a goodly gathering of scientific men, including Professors Playfair, Owen, and Tyndall, Sir Henry Holland, M. Dumas, Sir Roderick Murchison, Dr. Billing, &c. From the opening remarks of the Prince of Wales, it appears that early in 1868 the council of the Royal Society requested their president to take measures for bringing forward a proposal for a memorial to Faraday, and it was forwarded to the following societies, with a request that they would join with them in the endeavour to carry out that object, namely:—The Royal Institution, the Royal Geographical Society, the Royal Chemical Society, the Geological Society, the Royal Astronomical Society, the Linnæan Society, and the British Associa-Linnæan Society, and the British Associa-tion. On the 24th of March, 1868, a meeting of the eight presidents of the Royal affiliated societies was held, and it was thought desirable by them to learn the views of the Government in record to the the views of the Government in regard to the erection of a monument to Faraday. On the 27th of June, 1868, Mr. Disraeli asked his secretary to write to the effect that he considered the erection of a monument to Professor Faraday to be a proper object to which to devote public funds; but that as the esti-mates for the year had passed, any vote for the purpose must be deferred to the following year. On the 8th of May, 1869, the present Chancellor of the Exchequer wrote that, chancellor of the Exchequer wrote that, while fully concurring in the propriety of erecting a monument as proposed, he could not, as Chancellor of the Exchequer, consent to the appropriation of public money for the erection of a monument to any private citizen, however eminent; adding that "he did not be the other than the found in the country to th not make that rule, but found it." 8th of June, it was resolved that a meeting should be held at the Royal Institution, which is the meeting in question.

General Sabine, in a few appropriate re-

には、

ESSII

SIE

marks, moved the first resolution, which was "that it is desirable that measures should be taken to provide a public memorial to Faraday." The motion was seconded by M. Dumas, who highly culogized the talents and learning of the late professor. The motion having been put and carried unanimously, Sir Henry Holland moved, and Sir R. Murchison seconded, a resolution, "That a committee be appointed to take the necessary measures for the provision of a public memorial." This resolution having also been carried, Professor Owen moved, "That a public subscription be entered into, the subscriptions not to exceed five guineas in each case, in order to raise the requisite funds."
Professor Playfair seconded the motion which was also carried. After this, Sir Henry Holland moved a cordial vote of thanks to His Royal Highness, for his conduct in the chair. Professor Tyndall seconded the resowho, in thanking the meeting, gave his assurance that if anything more could be done in the matter by him, he would always be at their service. We trust that now the matter has been set fairly afloat, the necessary machinery will be organized, and the necessary funds collected, by which honour will be done to the memory of one whose name occupies so distinguished a position amongst terial, Mr. Fletcher suggests that the plates used in the construction of boilers should not only be branded or stamped, like silver, with a certificate of quality, but marked also with the name of the manufacturer, so that the responsibility of the work could always be brought home to him. Then, with regard to the fittings, we all know how easy it is to intainted. Perhaps, as a rule, little more that can be made. It is open to the consumer to adopt the same means of obtaining the greatest amount of light possible from the gas supplied to him. How much light is brought home to him. Then, with regard to the fittings, we all know how easy it is to intainted. Perhaps, as a rule, little more that can be made. It is open to the consumer to adopt the same means of obtaining the greatest amount of light possible from the responsibility of the work could always be brought home to him. Then, with regard to the fittings, we all know how easy it is to intainted. Perhaps, as a rule, little more that can be made. It is open to the consumers to adopt the same means of obtaining the greatest amount of light can be made. It is open to the can be made. It is open lution, which was responded to by the Prince,

those of scientific men. For our own part, we shall be happy to place our journal at the service of the committee when formed, with the view of promoting an object in which all classes of society cannot fail to take an interest.

#### THE BINGLEY EXPLOSION

THE fatal boiler explosion at Bingley, which caused the death of fifteen persons, and injured about twenty-five more, has been the subject of investigation by Mr. L. E. Fletcher, Engineer-in-Chief to the Manchester Steam Users' Association. The examination was made at the instance of the coroner, who very judiciously adjourned the inquest pending Mr. Fletcher's report. That document has now appeared, and, from a perusal of its contents, it appears to us mira-culous how the boiler lasted so long as it did. It was of the type usually employed in the Lancashire and Yorkshire mills, but was constructed of inferior metal, and so was wrong from the first. Previously to being wrong from the first. Previously to being put to work at Bingley, it had seen some eight or nine years' service in another establishment. When it left the latter place, it was purchased by a boiler maker, repaired, and resold. The repairs were necessitated by external corrosion underneath the boiler, but they were imperfectly done. Half-inch plates were riveted on to the old plates where they had become worn to a quarter of an inch. Thus patched up, the boiler lasted three years, when it exploded with the fatal effects we have mentioned. From an examination of the fragments, Mr. Fletcher found that leakage began at the junction of the old and new work. In more than one place, the plates were found to be reduced to the thickness of a sheet of paper—the old, old story. Of course, the shell gave way here, and the rent proceeding thence through the addiction relates soon completed the dethe adjoining plates, soon completed the destruction of the boiler.

But the piece of patchwork was not the only fault the boiler had; it was badly equipped, and badly tended as well. The safety valve was too small and of defective construction, and the engine tenter is be-lieved to have been both incompetent and reckless—two conditions generally found as-sociated together. Mr. Fletcher, however, very properly observes that some more prac-tical lesson should be drawn from this fatal catastrophe than to throw the onus of fifteen deaths upon an ignorant stoker already killed by the explosion. The jury, however, eturned a verdict of manslaughter against the dead stoker, and censured the owners of the mill for employing so incompetent an attendant and leaving him without supervi-sion. They also recommend that all boilers should be brought under Government inspection, and there the matter rests. But the circumstances attending the construction and use of this boiler call for further remark here. We have over and over again pointed out how really preventible are those explosions, and that, therefore, they do not properly come within the meaning of the term "accident." It is needless to observe that this boiler was not under inspection, or it would have been condemned three years since. Had it been properly constructed at first, and placed under the protective inspections of the companies formed for this purpose, it is highly improbable that the recent catastrophe could have occurred. To guard against the possibility of bad ma-terial, Mr. Fletcher suggests that the plates

Bingley explosion is only a repetition of an oft-told story, which must lead to protective legislation if repeated in the highly culpable form it has here assumed. Such events make us look with anxiety to the work the committee of the Manchester Steam Users' Association have taken in hand, for promoting the security of life and property against unsound boilers. They propose that coroners should be empowered and instructed to command the attendance of competent engineers to give evidence when conducting enquiries in reference to these disasters. This would in reference to these disasters. render unnecessary any Government action, which might prove an interference with the freedom of the steam user, but to which he will inevitably have to submit if he does not mend his ways.

#### THE REPORT OF THE GAS REFEREES.

THE second report of the Gas Referees, just presented to the Board of Trade, deserves a notice, from the insight it gives us into what the referees have been doing. In the first place, they tell us that the testing stations are ready, and that they have caused them to be fitted up with "improved forms of Bunsen's photometer." This means, we read in the "Journal of Gas Lighting," in every instance but one, Mr. Evans' photometer, which very few regard as an improved form of Bunsen's. But we may let that pass. The referees go on to say that they regard our present system of photometry as very defective—the coincidence of which opinion defective—the coincidence of which opinion with that invariably expressed by gas examiners is truly remarkable. But they go on to say, that "a slight variation in the sensibility of the eye of a gas examiner may easily make a difference of half a candle in his recorded testings." That eyes do vary in sensibility must, we suppose, be accepted as a fact, although the thing is difficult to prove. But what the referees do not say is, that an eye is just as likely to be over as under sensitive, and that an error is just as likely to be in excess as the other way. And, likely to be in excess as the other way. And, further, that if we suppose a fatigued eye, the under-sensitiveness will be exhibited as much on one side of the photometer as the other, and thus the result will be just as accurate as if there were no variation in sensibility at all. The object of the paragraph, however, is tolerably evident. It reads like an "instruction" to the Chief Examiner that it would be extremely unjust to fine a gas company for a deficiency of half a candle in illuminating power, and, as such, will no doubt receive its full appreciation. If this variation in the sensibility of the eye be admitted there is of course and to all the sensibility of the eye be admitted there is of course and to all the sensibility of the eye be admitted there is of course and to all the sensibility of the eye be admitted. mitted, there is, of course, an end to all modes of photometry in which the human eye plays any part; and as the referees feel it incumbent on them to discover, if possible, some better means, they must find one which altogether dispenses with the use of this variable organ.

The mode of discovery adopted by the referees is not one usually practised in scien-tific pursuits. It is one, however, by which people often get what they want—namely, by advertising! They advertised for a burner, and "discovered" Mr. Sugg's London argand, which they have adopted as the standard burner. Against this adoption there is nothing to be said. It is, unquestionably, the best burner for common gas yet invented, and the gas companies have a right to be tried by the very best standard

Digitized by GOOGLE

fective burners they employ. We quote the cause of this, as stated by the referees, which will not be flattering to many of our readers -"With one or two exceptions," they say, "the manufacturers of gas apparatus are wholly ignorant of the principles which regulate the development of light from gas; and, in consequence, the market is filled with bad burners, when good ones might be had quite as cheaply." We recommend the manufacturers of gas apparatus to take this sentence to heart, together with some other statements made by the referees. They tell us of the smaller burners—bat'swings and fishtails—that they are so carelessly made that scarcely any two professedly of the same character will agree in the amount of same character will agree in the amount of light they give; that fish-tails are especially bad, some giving only 24 and 23 of the light they ought to yield. This is a grave but, no doubt, a true statement, the publication of which will, we hope, lead to improvement. It seems clear from this that undeserved blame is often thrown upon gas companies. The public complain of the gas when their burners are at fault. It is quite right of the gas referees to point this out, even if in so doing they step a little out of the track prescribed for them by the Act of Parlia-

But what is the immediate effect of the location of the new standard burner? The adoption of the new standard burner? light given by the old standard, equalling 100, as they say, the new burner with the same gas gives a light equal to 116. In other words, supposing the gas is 14 candles by the old, it will be over 16 candles by the new standard. Thus by a stroke of the pen, as we may say, the referees have at once raised the quality of the gas to the standard which will be required after the 1st of January next. The gas companies ought to be infinitely obliged to them, and still more to Mr. Sugg.

Now, supposing London tolerably lighted with our present gas supply, and the almost universal use of bad burners—and that such is the fact, nobody will deny—every one will agree with the referees, that by the use of good burners "a satisfactory amount of illumination could be secured with an increased use of cannel coal." This is said on page 4, when illuminating power is in question. But when illuminating power is in question. But presently we come to the question of the amount of sulphur to be allowed. This seems likely to be settled by the referees some time in the Greek Kalends. They have cut out an immense amount of work to be done before they can decide on a maximum for sulphur. But having just now said, and, indeed, made it perfectly clear, that gas may be raised two candles in illuminating power, without any additional use of cannel coal, they tell us, on page 8, when sulphur is in question, that this increase of two candles "can only (so far as is yet known) be attained by using cannel coal in larger proportion than at present, and cannel coal usually contains a larger proportion of sulphur compounds than common coal does." After this, we can only expect a liberal allowance of sulphur for the gas com-

It is unnecessary to say much about the modes of estimating sulphur in gas. referees have a perfectly accurate one in Mr. Valentin's process, but it is not very easy to carry out. Dr. Letheby's method has been Dr. Letheby's method has been adopted provisionally, but the referees say that they have convinced themselves by experiment that it does not afford a perfect criterion of the amount of sulphur compounds in gas. This is another remarkable coincidence in opinion, for neither Dr. Letheby nor anybody else has ever said that the process could be relied on as a perfect criterion. However, the referees have devised a process of their own to meet the requirements of the case, which they have submitted to Drs. Odling and Frankland, whose report is waited

for.

The amount of ammonia now allowed is, as

our readers know, five grains in 100 cubic feet. This by weight forms only 1-4000th part of the gas. By combustion, ammonia is converted into nitrous acid, and supposing the 100ft. of gas burnt in a room 20ft. square by 12ft. high, the nitrous acid would form 1-640,000th part of the atmosphere of the room if it remained unventilated. By this state-ment, it is insinuated that five grains of ammonia can do no harm. Nay, the referees say, by some chemists—by whom it is not said—ammonia may do good, since it tends to neutralize the sulphurous acid formed in the combustion of the gas. How nitrous acid neutralizes sulphurous acid it is difficult to see. That it may assist in converting sulphurous acid into sulphuric, and so assist in doing harm, is more than probable. But, indeed, the combustion products of ammonia are of small consequence. It is the mischief done to gas fittings by ammonia itself that makes it so desirable to get rid of it, and we read with some satisfaction that the referees have made up their minds that eventually it shall be got

The general remarks which conclude the report we have read with some astonishment. The referees take credit for having done all in their power to save expense both to the municipal bodies and the gas companies. They wished to have as few testing places as possible; but as the companies insisted on having the tests made as near as possible to the 1,000 yards, the referees acceded. Nobody supposed for a moment that they would do otherwise. But the absurdity of the limitation remains. Gas need not and ought not to lose illuminating power as it travels; and if the companies' mains extend ten miles, the consumer at the end of the distance is entitled to as good gas as another close to the works, for he pays precisely the same for it. Profiting by the example of the gas companies, we may expect that when the next Adulteration Bill comes before a committee, the dairymen will insist on having their milk tested close to the cows' teats, and not at the extremity of their milk walks, for milk often loses in inchange in the control of the company of the compa richness as it travels. And there is evidently some of the milk and water of human kindness in the referees. If they suggest to the corporations that they have made the work of an examiner so simple that he need only be paid a small salary for doing it, they tell the examiner that they have studiously en-deavoured to occupy as little of his time as possible. And yet, mindful as they are of corporations and examiners, they have not forgotten the interests of the companies, and so have put "ample checks upon the gas examiners." We believe that all the referees are not entirely destitute of modesty; but, really, this is going too far. For men who became acquainted with gas analysis but yesterday, to boast of having put "ample checks" upon such examiners as Mr. Keates and Mr. Heisch, is simple impertinence.

### THE ANGLO-MEDITERRANEAN TELEGRAPH COMPANY.

LTHOUGH the Company has been in A existence for a short time only, and commenced working their traffic in October last, after the successful submersion of their deep-sea cable, they have just declared a dividend at the rate of 10 per cent. per annum. This should give great encouragement to investors in submarine cables. The directors report that, "since the issue of the last report, the British Indian Submarine Telegraph Company has been established for the purpose of laying a cable from Suez to Bombay. A mutually advantageous arrangement for the exclusive interchange of traffic between this Company and the British Indian

returns upon their capital." In the original contract, when this Company was established, it was agreed that the Anglo-Mediterranean Company should pay to the Lords Commissioners of Her Majesty's Treasury the sum of £2,000 per annum, it being understood that the then existing Malta and Alexandria cable be abandoned from the date of the laying of the new cable.

The old Malta and Alexandria cable has seen vicissitudes. Destined originally for Rangoon and Singapore, it was unfortunate in its departure from this country. The vessel carrying a portion got ashore, and innumerable delays occurred, and, finally, its destination was changed; and, in the autumn of 1861, it was successfully submerged between Malta and Alexandria. As a rule, it may be safely taken that a cable, specially designed for one place, is not the most appropriate for another place; but there was the cable, and the result is no exception to the rule. The cable, not being intended for deep rule. The cable, not being intended for deep water, was submerged in generally very shal-low water. It was first laid from Malta to Tripoli, and from Tripoli along the coast to Alexandria, touching at Benghazi. The sections from Tripoli to Alexandria were laid pretty close to the shore, and with some difficulty, as the route had to be sounded all the way and carefully buoyed, the water being found generally to deepen suddenly. The cable, after submersion, was soon in working order, and found to answer admirably. But, in 1863, the first mishap occurred. An interruption took place; these yearly became more frequent, involving a large amount for repairs, besides causing lengthy interruptions to traffic. The result has been the successful establishment of the new line, and the agreement for the abandonment of the old line. This, we are glad to say, is not to be carried out. It would be a sorry fact to record that such a length of cable was entirely abandoned.

By mutual arrangements between the Treasury, the Anglo-Mediterranean Company, and the Telegraph Construction and Maintenance Company, it has been determined to put this cable in good working order again; and we hear that, after a careful examination of the cable, it has been determined to make it a cable, it has been determined to make it a reliable alternative line, to remove all the existing faults, and to carry into deeper water those portions now lying in rocky ground near the headlands on the African coast, where most of the faults have occurred. For this purpose, 48½ miles of new cable have been purchased. This, in addition to 33 miles in stock at Malta, and a large amount lettly interested in the selle will it is absorbed. lately inserted in the cable, will, it is believed, be sufficient to place the cable in thoroughly good and, it is to be hoped, in more permanent working order. This arrangement must be considered as most satisfactory, as a duplicate line will then be at work between Malta and Alexandria. Our traffic with the latter place is most important, and our through traffic to India considerable. This latter, on the completion of the British Indian cable, will be largely increased, and the certainty of transmission will be rendered more probable by there being an alternative route.

### IMPROVED REFINING PROCESS.

TT is rapidly being understood that in the various semi-mechanical, semi-chemical processes which are inseparably connected with many of our industrial arts, nothing should be permitted to be lost. Formerly, when deleterious gases were generated during any chemical operation, attendant upon the manufacture of any article, it was considered the height of ingenuity to devise means by which they might escape from the neighbourhood of the premises and the workmen where Company has been concluded, and the directors congratulate the shareholders upon the prospect of increased traffic and increased vert a noxious and disagreeable substance into

a valuable article of commerce—the object NOTES aimed at was to get rid of it at any price. No matter what might be the nature of its constituents, no matter what valuable ingredient might be carried along with it in its course, the object was to let it get away, and distilled gold would have been given to the winds with the same recklessness and heedlessness with which a man would blow a whiff from his pipe. Provided the ultimate result of the operation was attained, manufacturers paid little attention to the host of miscellaneous substances, solid, liquid, and gaseous, which appeared, as it were, to be insignificant contingencies upon the formation of the product desired. Since this reckless disregard for these accidental productions has given place to a careful study of their nature and properties, and the best manner of preserving and utilizing them, it has happened that in some instances the conditions have been reversed. That which was formerly thrown away as possessing no value of any kind, is now esteemed far more than the substance, for the production of which the whole process was conducted. As the alchemists of old, in their of old, in their insane search after the philosopher's stone, or the fabled transmutability of metals, discovered accidentally numerous rare and important substances, so have our own chemical operations been productive of useful and valuable results. There is scarcely a single process now, in connection with manufacturing and industrial arts, into which a most rigid and searching scrutiny has not been made, with the view of detecting the escape of any valuable and convertible ingredient, and taking measures to utilize it. It has been remarked that "nothing in nature is lost, and there is no reason why the same truth should not hold good in the numerous operations attendant upon the daily advancement of chemical and mechanical science. refining of the precious metals is a process which has existed from the earliest times, and which, with many improvements, has been handed down to the present day. Its principal feature consists in dissolving in concentrated sulphuric acid particles of silver and copper. During the operation, vapours of sulphuric and sulphurous acid are disengaged and conducted by leaden pipes into the condensers, which are filled with cold water, and subsequently into leaden chambers or receptacles, where a portion of the sulphuric acid is condensed. The sulphurous acid suffers little or no condensation, but escapes up the chimney as well as the remainder of the sulphuric acid, which has likewise not been condensed in the chambers. With a view of preventing so serious a loss of a very useful chemical reagent, M. Dubois-Caplain has recently patented an improvement upon the process, which is likely to prove of some importance.\* Instead of leading the gases and vapours simply into cold water, he introduces into the chambers appropriated to their reception and condensation, a quantity of very fine wrought-iron shavings or strips. He also brings them in contact with a jet of steam, situated in the line of draught. Under the combined action of the steam and the iron, the two acids are decomposed, and sulphate of iron is formed, which passes off in a state of solution. A double object is thus effected. Not only are the deleterious gases absorbed and rendered innoxious, but they serve to produce a substance which is both valuable in itself and is also one for which a ready sale is always to be found-a most important consideration when a bye product has to be disposed of. Whatever metal may be substituted for the iron, although the product will be different, the reaction will be the same, provided always that the metal be attackable by the acid in question, a circumstance that can be ensured a priori.

ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL AP-PLICATIONS.

BLACK LEAD AS A LUBRICATOR FOR ALL MACHINERY THE CENTRIFUGAL EXTRACTOR FOR WINE AND CIDER MAKING -A NEW SYSTEM OF KEEPING BEER ON DRAUGHT.

BLACK LEAD, which has only been used as a lubricator for wooden machinery, is now applied by M. Deloris to every kind of machine, from the heaviest vehicles to the most delicate watchwork, so dispensing with the use of oils and grease of all kinds. We are not yet informed of the manner in which the plumbago is employed, but if it can be successfully applied to railway carriages, a great saving to the companies will be effected. It is said to be used with many vehicles in Paris, and in machinery at several factories, and seems to give satisfaction.

The centrifugal machine has been applied with great success in France to the extraction of the juice of grapes and apples for wine and cider making. It is found to get out considerably more juice, and to be much more rapid in its action. It is found to get out considerably more It did with grapes, for example, in two hours more work than the press did in seventeen hours, with quality, while, with the press, it is found that it is only the first runnings which will make wine of the best quality, the long contact of the rest with the skins and stalks rendering it fit only for wines of inferior quality. In the case of cider, the use of the machines seems equally advantageous, much less juice being left in the marc, and the extraction being effected with great rapidity. The amount of force required to give a machine of the necessary size a thousand turns a minute, does not exceed that of a three-horse engine.

A very ingenious plan of keeping beer on draught completely excluded from air has been devised by Mr. Taylor. It dispenses altogether with the use of casks. A slate cistern is let into the ground, by which at once the advantage is obtained of keeping the beer at a nearly uniform temperature at all seasons of the year. But, as we have said, the all seasons of the year. But, as we have said, the chieffeature is the complete exclusion of air. This is effected by the use of a floating lid, which, of course, descends as the beer is drawn out. manner in which the lid is made to fit accurately to the walls of the cistern, and still is free to descend, could only be made clear by a drawing. But we may say that a wooden lid is made to fit very nearly to the sides. The sides of the wood are bevelled, so that only a narrow edge is presented to the walls of the cistern. Along this edge a band of canvas or india-rubber is fixed, which gives, with the bevel on the upper surface, which gives, with the bevel on the upper surface, a V-shaped space, and by packing this space with wet sand, or some soft material, the canvas or india-rubber is kept in close contact with the walls of the tank. Thus, the liquid within is completely sealed from all access of air. In corder to draw out the hear the centre of the lid is order to draw out the beer, the centre of the lid is bored, and provided with a stuffing box arrangement. To tap it, a perforated pipe is thrust through the stuffing box, and the connections to the beer engine are made in the usual way. This pipe deserves some notice. It is closed at the bottom and for an inch or so up, so that, when the lid descends to the bottom, any sediment in the tank is avoided. In this way, the beer is always drawn bright and clear. The advantages of totally excluding air from beer are very great, both to brewer and publican, whose greatest loss is made by beer turning sour, which will be en-tirely prevented by the use of this apparatus. There will be an enormous incidental saving in the cost of casks. Besides that, all the dangers of foul casks are avoided. For publicans who brew their own beer, the plan offers peculiar advantages, for the tanks will serve as fermenting vats, and besides that, they need not have a cask in their establishment.

# PARLIAMENTARY NOTES.

VESTERDAY week, Lord G. Hamilton asked the Chief Commissioner of Works whether any arrangement could be made at the Royal Botanical Gardens, Kew, whereby the public could be admitted at an earlier hour than at pre-

Mr. Layard observed that these gardens were Shortly afterwards, Sir J. Elphinstone asked the maintained for scientific purposes as well as for First Lord of the Admiralty if he would state the

pleasure, and it was in consequence of work that had to be done in the hothouses and elsewhere that it was thought necessary to keep the gardens closed until one o'clock. He trusted, however, that he might be able to make some arrangement to admit the public earlier than was the case at present

At the same sitting, Lord Garlies called attention to the armament of the sea and land defences constructed and in process of construction at Portsmouth, Plymouth, &c., and asked the Secretary for War the amount provided in this year's Estimates for such armament, independent of any saving which might be effected by the probable adoption of the Monerieff system. He said that up to June last no less than £5,118,000, or twothirds of the whole calculated sum, had been expended upon the fortifications. This being so, it became important that they should know what preparations had been made for supplying the armament of these forts.

Mr. Cardwell said that as to our land defences. there were in store now more guns than would supply the defences. As to the sea defences, there were not guns enough yet made, but there were more than could at the present moment be mounted, and the supply was gradually and steadily increasing. In reference to the amount proposed in this year's estimate for armaments, 99 10-ton guns were provided last year, and a similar number would be provided this year. This statement was not literally an answer to the noble lord, but it really gave the information he

On the motion for going into supply, Mr. M. Chambers called attention to the anomalous posi-tion of the clerks of the works and clerks of the Royal Engineer Department, and the denial pensions to their widows, and moved, "That in the opinion of this House they are entitled to, or should be granted, the same rights and privileges, according to their relative rank, as are extended to other non-combatants in the military service." Mr. Chambers argued from the terms of the Royal warrant that the widows of these clerks were en-titled to pensions the same as widows of military officers, and he added that the dangers of war, to which, as well as to the dangers arising from climate, they were often exposed, furnished an additional ground for giving pensions. It might be said that the clerks might insure their lives, but they could not do this without forfeiting their insurance when they went on foreign service, or without paying such an amount of premium as could not be spared

out of their salaries. Captain Vivian said that those clerks were to have "relative rank" with military officers of a certain grade; and the question was whether that provision entitled their widows to pensions. were really not exposed to the dangers of war, and that was shown by the fact that only two of them were employed during the Crimean campaign, and they were at Scutari. The warrant under which pensions were now asked for had nothing to do with pensions, but only with pay and allowances. He did not think that those clerks had any reason to complain. As far as their duties were concerned, they had no title to any pension allowance, or extra pension. Their case had on three or four occasions been carefully investigated, and had been decided against them, and he hoped, therefore, that the hon member would not press his motion to a division.

Mr. Maguire supported the motion, and contended that where an officer sacrificed his life in the public service his widow was entitled to a pension. He did not think the answer of the Government satisfactory.

After a few remarks from Mr. Cardwell, who observed that they were all economists in the abstract, yet when particular cases like the present arose, the Government were pressed to yield, and that it would be impossible to enforce economy if motions like the present were agreed to, the motion was withdrawn.

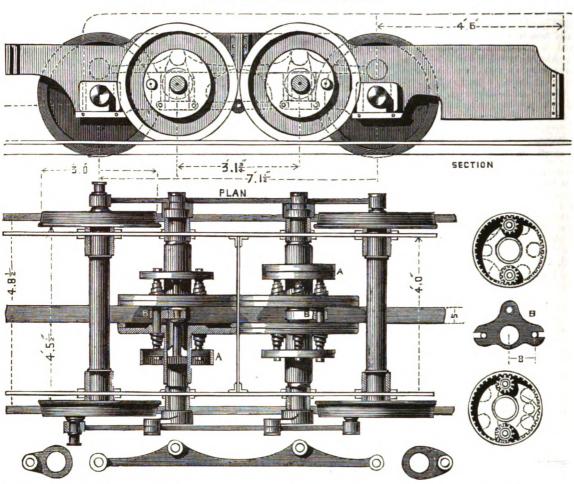

On Monday evening, Sir S. Northcote asked the Under Secretary of State for India whether the Government were taking any steps for the preservation of the fisheries in those rivers in India and Burmah where irrigation works had been constructed or were in contemplation.

Mr. G. Duff said Dr. Day, the author of the "Fisheries of Malabar," had been appointed to examine into the whole of that important subject. The Secretary of State had just sent out a dispatch to the Governor-General to give every encouragement to those officers who showed an intelligent interest in the fisheries.

<sup>\*</sup> We extract the description of this recent patent from our excellent cotemporary, "Le Genie Industriel."

#### MOUNTAIN LOCOMOTIVE. DESIGN FOR

BY MR. A. ALEXANDER, C.E.

reasons which induced the present Board of Admiralty to reverse the decision of their predecessors, and permit the extension of Ryde Pier to the westward; and whether the proposed extension was not the subject of inquiry by the late Board of Admiralty, and refused by them on the ground that it would interfere with the navigation of that part of the Solent.

Mr. Childers said there were two piers at Ryde belonging to joint stock companies. An application was made by the companies to the late Board of Admiralty to allow of an extension of the western pier to enable a ladies' bathing place to be erected there. It was strongly supported by the local authorities of Ryde, but objected to by the owners of lighters and coasting vessels, on the ground that it would diminish the access to the small landing place between the two piers, and the late Board disallowed the application. The application was renewed to the present Board, and, a recent occasion, he had made a personal inspection of the locality, as he found that the officers who refused the application were divided in opinion upon the matter. In that personal inquiry he had the assistance of two distinguished officers—Sir Sydney Dacres and Admiral Simonds, who were of opinion that, with a modification of the plan, no interference with the navigation would take

#### THE FRENCH ATLANTIC CABLE.

THE following telegram has been received from Captain Donaldson, of the steamer William Cory":

"ST. PIERRE, NEWFOUNDLAND,

June 23.

"Arrived here to-day; all well. Will leave this evening to proceed with the work of laying the St. Pierre shore end."

Sir Daniel Gooch, Chairman of the Telegraph Construction and Maintenance Company, telegraphs as follows:-

"Great Eastern," June 23.
"Distance run from Brest, 294 knots. Cable paid out, 310 knots. Electric condition perfect."

#### DESIGN FOR A MOUNTAIN LOCOMOTIVE.

N our notice of the conversazione at the Institution of Civil Engineers, we referred to a model of a mountain locomotive, by Mr. A. Alexander, C.E., the designer of the Mont Cenis locomotives. We now illustrate Mr. Alexander's present proposition for working the mid-rail system. At each side of the mid-rail are mounted a couple of disc wheels, a portion of the faces of which, near the periphery, rest against the mid-rail. This last may consist of a bar not more than three-quarters may consist of a bar not more than three-quarters of an inch deep, gripped between the opposing whoels on horizontal axles. The wheels are forced against the rails by volute springs in the following way:—The mid-rail wheels are driven by crank pins passing through the arm B, which is solid with the shaft. A transverse brake shaft is carried between the two mid-rail axles which works friebetween the two mid-rail axles, which works friction straps upon the drums A A, the effect of which is to tighten up the screws, and through the medium of the six or four volute springs behind each pressure plate, to force forward the mid-rail each pressure plate, to force forward the mid-rail wheel to the amount required. This scheme appears to be the best solution yet offered of the mid-rail difficulty. We get rid at one sweep of an immense mass of complicated machinery; two outside cylinders—not shown—working in the ordinary way, with outside valve gear, supply the power required. The ordinary features of the locomotive are all retained, and the weight and cost of the machine are enormously reduced. No difficulty motive are all retained, and the weight and cost of the machine are enormously reduced. No difficulty will be encountered in keeping oil off the mid-rail— a very great difficulty with the present Mont Cenis engines; and, all the bearings being horizontal, the oil will not tend to run down the shafts and

tice Bovill undertook himself to settle the terms of the rules for constituting the proposed court. The matter was heard by his lordship in chambers on the 8th inst., was then fully argued by counsel, and the rule has been since finally settled. following are the matters referred to the arbitra-ment and determination of the court:—1. The reduced to the 12s. 10d. question, the cost of the parchments and engrossments, to be considered on legal and moral grounds. 2. The claims of Mr. Edmunds against the Crown, as appearing on the accounts and proceedings in Chancery, also to be considered on legal and moral grounds. 3. The claims of Mr. Edmunds against the Crown, for damages and compensation, in consequence of the alleged libellous and defamatory reports of Messrs. Greenwood and Hindmarch, and the subsequent proceedings of the Government thereon in Parliament, in the courts of law and elsewhere. The court to sit in public. The action for libel ("Edmunds v. Greenwood") thus referred, is, in fact, a proceeding against the Crown; it has been so dealt with throughout by the Crown officers; and Mr. Greenwood, the nominal defendant, servant of the Treasury, and author and publisher of the reports in question, is indemnified by the Treasury against damages and costs.

VISIT OF WORKING MEN'S CLUBS TO THE NEW BUILDING OF THE UNIVERSITY OF LONDON.

the machine are enormously reduced. No difficulty will be encountered in keeping oil off the mid-rail—a very great difficulty with the present Mont Cenis engines; and, all the bearings being horizontal, the oil will not tend to run down the shafts and away from the rubbing surfaces.

THE EDMUNDS CASE.

THE questions as to the terms of reference to an open court of arbitration of all matters in dispute between Mr. Leonard Edmunds and the Crown (proposed by the Crown officers for the third time in January last, and which have been in one form or other in dispute for two years and a-half), have at last been settled, and the court of arbitration constituted. It will be recollected that, at the last hearing in open court, the Lord Chief Jus-

THE IRON AND STEEL INSTITUTE.

N Wednesday evening last, the members of the Iron and Steel Institute held their first meeting in the rooms of the Society of Arts. The objects of the Institute are to afford a means of communication between members of the iron and steel trades upon matters bearing upon the respective manufactures, excluding all questions connected with wages and trade regulations, and to arrange periodical meetings for the purpose of discussing practical and scientific subjects bearing upon the manufacture and working of iron and steel. The meeting was fully attended, and was presided over by the Duke of Devonshire, who delivered an inaugural address of considerable length, and greatly to the point. The president reviewed the success which had attended the formation of scientific and agricultural societies, and saw no reason why equal advantages should not accrue to the iron trade by association. Then his Grace passed on to review the early history of iron, the manufacture of which was mentioned by Homer and Hesiod, and had been asserted by Mr. Layard to have been known in Assyria in 900 B.C. He then noticed the early methods of manufacture down to the period of the use of coal, which gave such a vast impetus to the manufacture of iron in this country. He often work a proposed to the invention country. He afterwards referred to the invention of the "hot blast," the increased supplies of ore, and other causes which had contributed to the present importance of the iron manufacture. The processes by which pig iron, malleable iron, and steel are manufactured having been alluded to, the president referred to the utilization of the waste of gases from the blast furnaces; and went on then to show how the raw material and manufacture were distributed over the world. His Grace observed that the problems to be solved now which were of the most importance were, economy in the consumption of fuel, and a greater utilization of the waste gases. Mineral oil had been used in the dockyards in place of coal. It was also highly important to obtain the metal as pure as possible, and though chemistry had been brought to the aid of the manufacture, yet the chemistry of iron and steel was still, in many respects, obscure and uncertain. We hope shortly to print this interesting address

#### ON THE CAUSE OF A PINK COLOUR IN WHITE LEAD CORROSIONS.\*

BY MR. WILLIAM BAKER, F.C.S.

TN some contributions to the metallurgy of lead published in the "Philosophical Magazine 1862, I attributed a contain min." , I attributed a certain pink tint, occasionally seen in white lead corrosions, to the presence of small quantities of copper. As the results of any experiments upon the corrosion of lead by the combined action of fermenting bark, acotic soid vapour, and atmospheric oxygen can only be arrived at after the expiration of ten weeks or three months, the progress of further investigation in this matter has been necessarily slow. I have been unable to isolate the colouring matter; but I wish to correct the statement that the pink colour is due to copper, and to detail some conclusive proofs that it is caused by finely-divided silver.

roofs that it is caused by finely-divided silver.

Having obtained many tons of lead which contained only traces of copper, I found in several instances the pink colour still quite evident in the corrosions. By the method which had been employed for refining the metal, there could be only silver left as an impurity in any perceptible amount. I therefore sought for evidence that this substance could produce such a result. Upon analyzing 5,000 grains of a perfectly white corrosion, and one which was distinctly and uniformly pink, the which was distinctly and uniformly pink, the result showed that the composition of the two samples differed mainly in the amount of silver:—

CuO. FeO. NiO. Ag. -0050 -0022 trace -0005 per cent. -0060 -0022 -0013 -0058 ,, White corrosion Pink corrosion

A small quantity of silver was then added to a portion of the lead which had produced the white corrosions, and this was again submitted to the corroding action. The result was a decided pink carbonate. This synthetical experiment was repeated many times with a like result upon various samples of lead which had before produced a white carbonate; and I find that the pink colour begins to show at the edge of the metallic portion left uncorroded when the silver amounts to more than loz. per ton of lead. A decided colour, which is uniform throughout the mass of the corrosion

is obtained when the silver amounts to about 11oz. per ton. A fracture of a dense corrosion often shows the crystalline character of the metallic lead, which is defined to some extent by the pink load, which is defined to some extent by the pink colour—as if the silver had segregated out at certain faces of the lead crystals. By the addition of a small quantity of arsenie or antimony, the pink colour was replaced by a dull purple; and a clear pink tint was only obtained when all the oxidizable metals had been removed.

I come now to the discussion of the state which the silver exists to cause a pink or reddish reflection of light. Silver does not oxidize under the conditions of exposure to acetic acid vapour and oxygen of the air. Moreover, oxide of silver and silver carbonate are themselves decomposed and reduced to a metallic state by a heat below that attained in the stacks of fermenting tan. The silver must consequently be in the metallic state. As confirming this statement, I made the following experiments:—Silver carbonate was triturated with white lead and water, and then dried. Upon increasing the temperature, a delicate pink tint became visible upon the reduction of the oxide of silver. If a small quantity of silver carbonate be precipitated along with lead carbonate, the colour, upon drying and heating, is more uniform, and it may be obtained exactly resembling the tint seen on white lead corrosions.

The colour of the photographs obtained by means of silver salts is also evidence in favour of means of silver saits is also evidence in ravour of the metallic state of the silver; and I may also adduce the fact that a ray of light, when reflected ten times from a polished silver surface, is dis-tinctly of a reddish colour.

#### CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

THE annual general meeting of this Society was held on Wednesday, the 23rd inst., at the Whittington Club, when the report of the council and financial statement was submitted and approved. On the retirement of the president and council from office, the members expressed themselves greatly indebted to the president for his services; also to the members of council. The following gentlemen were elected to fill the various following gentlemen were elected to fill the various offices for the ensuing session—1869-70:—As president, W. Forsyth Black; G. J. Crosbie Dawson and James B. Walton as vice-presidents; members of council, R. M. Bameroft, G. R. Godson, Frederick A. Klein, William Meaking, and Frederick H. Roberts; honorary secretary, G. W. Usill; and Arthur F. Pain as honorary treasurer.

Messrs, Roberts and Dawson having resigned their respective posts of honorary secretary and

their respective posts of honorary secretary and treasurer, which they have so successfully held for a period of nine years, and to whose efforts the members are greatly indebted, it was proposed and carried by acclamation, that the special thanks of the Society be presented them, suitably engaged and illuminated many reliable expressions. grossed and illuminated upon vollum, expressing the warm appreciation their services have given. Mr. G. W. Usill, late member of council, has agreed to act in place of Mr. Roberts, and from his previous exertions it is anticipated that he will prove a valuable officer; likewise Mr. Arthur F. Pain, who has consented to act as honorary treasurer.

It was resolved that the Society, for the future, should work under the Scientific Institution Act of 1864, and it was determined to hold during the recess the second annual dinner; likewise a conversazione. Numerous other considerations were versazione. Numerous other considerations were taken into account, but it should be mentioned that the society is in a very flourishing condition. Its objects are to avoid any attempt to compete with the older institutions, but to offer special facilities for the younger branches of the profession for reading and discussing papers, visiting works of importance Acc of importance, &c.

### SOCKET JOINTS FOR IRON PILES.

N constructing iron screw piles and columns, such as are employed in the erection of bridges, piers, &c., it has hitherto been customary to forge on one end of each length an enlarged portion, which is bored out to form a socket to receive the end of the next length. This method of construction is very costly, and also very imperfect, as the necessity of welding on the socket freed, quently leaves a portion of the pile unsound immediately above the socket. Another method ane objectionable on account of the liability of cast iron to sudden fracture. These couplings being necessarily made much larger in diameter than

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending June 19, was 3,395. Total number since the pening of the Museum, free daily (May 12, 1858), 1,589,261.

the pile or column, give it an unsightly and clumsy appearance. We are, therefore, glad to bring before our readers a method of coupling lately patented by Mr. Joseph Westwood, jun., of Tredegar House, Bow-road.

In constructing this improved socket joint, Mr. Westwood forms a tube of wrought iron or steel either by bending a plate of metal and welding its edges together, or by coiling a bar upon a mandril and then welding it, or by welding together a series of rings or hoops of the required diameter. The interior of the socket or tube is bored to fit the ends of the sections of the pile or column to be united. The exterior of the socket is then turned to give a neat and finished appearance to the work, or the exterior of the socket may be made hexagonal or of any other shape. The socket is then heated and tightly shrunk upon one of the sections The end of the section to be united or coupled to this section is then inserted into the socket, the two ends being made to butt together. Holes are then drilled through both the socket and the pile, into which holes keys are inserted and secured

#### THE CRYSTAL PALACE.

THE CRYSTAL PALACE.

The directors of the Crystal Palace Company have issued their report, which is very satisfactory, as showing that the arrangements for providing attractive entertainments for the public are proving successful, and that the financial position of the undertaking is becoming more encouraging. The station of the Metropolitan Fire Brigade on the roadfront of the Palace has been for some weeks occupied by the men and engines of the Brigade, so that the proprietors have now an additional permanent force in full efficiency, without any charge to the company for the increased security. The amount of insurance on the buildings and its contents is nearly £112,000. The Act of Parliament enabling the company to lease a portion of its surplus lands, the company to lease a portion of its surplus lands, which was authorized by the proprietors at the meetings of June and December last, has since received the Royal assent, and the directors are about to ask authority to exercise the powers obtained to grant building lease

Last Saturday, the rose show was held at the Palace, and proved one of the greatest successes of the season. Stands were erected along the centre of the naves, under an awning that extended the whole distance from the centre transept to the Tropical Department. On these stages, the roses, embracing overy hue from white to black, were fixed in vases, backed up by mossy banks, and so divided into sections that enabled the visitors to inspect them without the slightest crowding or inconvenience. Mr. C. Turner, of Slough; Messrs. Paul and Son, Cheshunt; Mr. B. R. Cant, Colchester; Mr. A. Moffatt, gardener to Earl Rosslyn, Essex; Mr. P. Stoddart, Colchester; Mr. W. Soder, Brentford; and Mr. H. Exell, Maidstone, were successful in gaining the first prizes for different varieties of roses. A grand musical festival, under the direction of the Sacred Harmonic Society, and conducted by Sir Michael Costa, is an val, under the direction of the Sacred Harmonic So-ciety, and conducted by Sir Michael Costa, is an-nounced for Tuesday, the 29th inst., in honour of his Highness the Viceroy of Egypt, upon which occasion he will be present. The orchestra will comprise be-tween 3,000 and 4,000 performers, and will bearranged as on the occasion of the Handel Festivals. There will be a display of the fountains in the afternoon, and another in the evening, at the time of the pyro-technic display. technic display.

### EMIGRATION TO THE RIVER PLATE.

EMIGRATION TO THE RIVER PLATE.

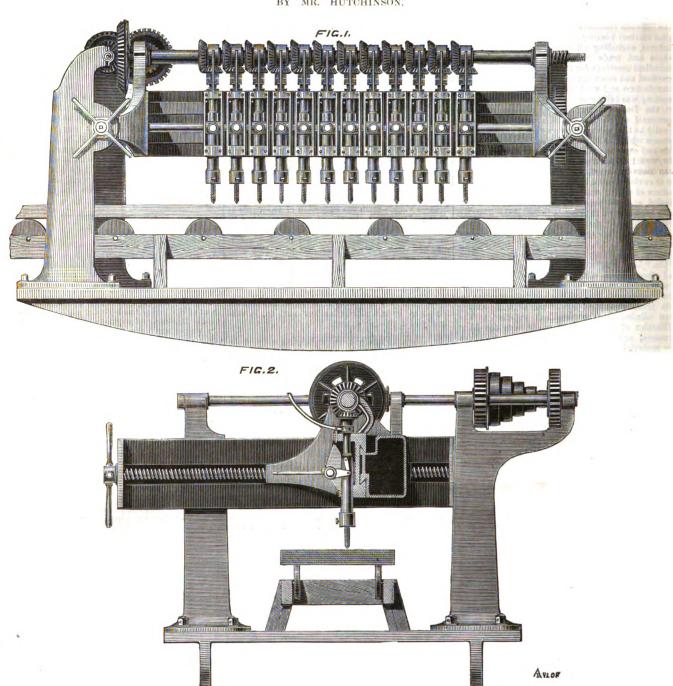

TOR some time past a series of most interesting letters have appeared in the "Field" newspaper, concerning the River Plate as a field for emigration, and having special reference to the domains of the Argentine Republic, and the inducements put forth by the rulers of that republic to intending emigrants. The letters are well worth perusal, and being written chiefly by persons who have themselves emigrated, have quite a practical value and importance. They have been collected into a pamphlet, which can be consulted with profit by any person interested in emigration schemes. They contain explanations of the most profitable systems of farming, and set forth clearly the various advantages which are held forth to emigrants. The Secretary of the Central Argentine Railway Company intimates that he will be happy to forward copies of the pamphlet on application, or to send them to any address furnished to him, and to give every information in his power respecting the lands for settlement ceded to the company on each side of the railway in the provinces of Santa Fe and Cordova. The company's office is 60, Gracechurchstreet, London, E.C.

Communicated by the Author to the "Philosophical

#### MULTIPLE DRILLING MACHINE.

BY MR. HUTCHINSON.

### MULTIPLE DRILLING MACHINE.

MACHINE which will be found extremely A useful to engineers, bridge and girder makers, shipbuilders, &c., is the multiple drill illustrated in the accompanying engraving. It is makers, shippunders, &c., is the mutiple drill illustrated in the accompanying engraving. It is the invention of Mr. Hutchinson, of the firm of Messrs. Pease, Hutchinson and Co., of the Skerne Iron Works, Darlington, who have several of them in use at their works with great advantage. These machines are made either stationary or portable; that illustrated by an absorpt to the forecast electric days are the stationary or portable. that illustrated by us belongs to the former class. They carry their own engine when required, and possess several important advantages; each drill is self acting separately, and adjustable in pitch separately, possessing more ready means of adjusting the pitch than has ever before being applied to multiple drills. Each drill has an independent frame and they can thus he readily set to any frame, and they can thus be readily set to any regular or irregular pitch. From our engraving, fig. 1 of which shows a front elevation and fig. 2 an end view of the machine, it will be seen that the whole drill-frame has a lateral motion, by means of which each row of rivet holes can be formed in succession. Each drill is also furnished with a small clutch and handle, and can be engaged or disengaged independently, this arrangement enabling a broken or blunt drill to be replaced without stopping the remainder. The feed is obtained by a double worm motion at one end of the framing

moving a shaft passing across the drill frame immediately in front of the drills; on this are double levers attached to links connected with the drill spindles, as shown in the engraving. Through the boss of each lever passes a large setpin, which at once serves to connect the self-acting feed and as a lever handle for withdrawing the feed and as a lever handle for withdrawing the drill. The driving shaft passes over the centre of the drills, driving each by means of a pair of bevel wheels. Where the girder or other work is composed of a number of plates, these machines, in combination with Mr. Hutchinson's continuous planing machine, are of special advantage. The plates and angle irons are drilled and planed in the position they will occupy in the finished work, and each row of rivet holes is made through the entire thickness at one operation. By this means. entire thickness at one operation. By this means, no drifting is afterwards required. As an instance of what these machines will do, we may mention that a 12-spindle drilling machine easily drills 2,000 holes per day ‡in. diameter through 9-16in. plates, and this with frequent variations of pitch. A planing machine with frequent stoppers for supplements. planing machine, with frequent stoppages for sup-plying fresh plates, &c., will plane forty super-ficial feet per day.

PHARMACEUTICAL CONGRESS, to which all civilized nations are invited to send representatives, is to take place at Vienna in September.

### NEW TYPE COMPOSING MACHINE.

NEW TYPE COMPOSING MACHINE.

P. R. C. E. REEVES, of 119, Collins-street East, study of mechanical type setting, and has at length designed a machine of which he sends us the following particulars. The composer's case, like the one at present in use, consists of shallow have and may year from 21st to 2st in length. like the one at present in use, consists of shallow box, and may vary from 2\frac{1}{2}ft. to 3ft. in length, and the same in breadth. Around the box, cells are placed to contain type not constantly required. The rest of the box is divided into two parts. These divisions are again divided by three plates, which are fixed in the sides of the centre piece of wood and the cells. Each of these plates has twenty-six grooves or notches, which vary in depth from an eight to a fourth of an inch. The grooves in the upper plate are different to those in the lower plates. They are notched to prevent the rod, which is run through perforated type, from tilting up when the lower extremity becomes beavier than the upper. A simpler plan than this tilting up when the lower extremity becomes heavier than the upper. A simpler plan than this has lately been used. It consists of a thin rod with notches to correspond, with the grooves in the lower plates, the heads of the rods being slipped under, and will be found to fix them much better. The type is perforated just above the centre. They are placed on the metal rod already mentioned, which is placed in the grooves. The type used has been perforated by hand. It is rather too

long, and cannot be used with the same facility as a shorter and more beadlike type, cast for the purpose. It is scarcely necessary to observe that small type will not admit of being perforated in the same direction as the large, but Dr. Reeves observes that they are easily turned when they descend into the composing stick. The composing stick works on rollers to enable the composer to move it freely with one hand, while, with the fingers of the other, he brings the type down. The proposed arrangement does not strike us as being at all calculated to facilitate the process of type setting, but rather to retard it; inasmuch as, after distribution, the types have all to be skewered on to the metal rods. In effect, this method would impose upon the compositor extra manipulation for every type, which, multiplied by 10,000—a day's work—would seriously affect his earnings and the work produced at the end of a week. We think Dr. Reeves had better try again.

#### BENTLEY'S SYSTEM OF WELL SINKING.

THERE are certain kinds of water-bearing strata, such as silt, quicksand, &c., from which it is difficult and even impossible, with ordinary appliances, to obtain a supply of pure water, although it may be present in abundance. With a view of overcoming this difficulty, Mr. J. F. Bentley, of Peterborough, has just patented the improved method of sinking wells illustrated in the accompanying engraving. The apparatus, as shown in fig. 1, consists of an iron cylinder α, the bottom of which is fitted with a cone b, or is provided with a conical end to which a socket c is attached. The socket is screw-threaded or chased so as to admit of the passage of the threaded end of the tube d. There are also a series of perforations in the threaded portion through which the water is admitted. The tube d is capable of being raised or lowered by being turned round in the usual way by hand or other power.

or lowered by being turned round in the usual way by hand or other power.

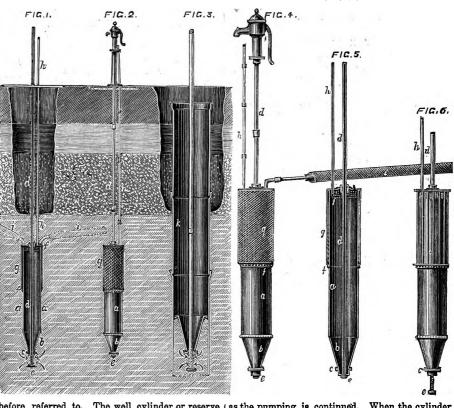

The use of the tube is first to draw up the silt or sand by means of pumping. For this purpose, the tube is screwed down until the lower perforations are below the conical end of the cylinder. A free passage for the silt or sand, mixed with water, into the tube is by this means provided, and, when a pump which is fixed on the top of the tube, as represented in fig. 2, is set in motion, the silt or sand and water are raised to the surface. Secondly, the tube, which is perforated at the bottom, serves to convey the water from within the cylinder to the pump. To effect this, the tube is screwed back or raised up so that a collar or plug e is brought in contact with the conical end of the cylinder, whereby a watertight joint is formed. This is done after sufficient silt or sand has been pumped up to allow the well cylinder to sink to the required depth. All the perforations are thereby brought up and raised within the inside of the conical end of the cylinder, thereby cutting off the connection between the bottom of the cylinder and the silt or sand and water outside. The tube d passes up the centre of the cylinder a, and through an opening provided in the top or cover. This opening is packed round the outside of the tube to stop the entrance of the silt or sand into the cylinder. The tube is continued upwards to the surface of the ground, and a common suction pump is attached to it. The detail arrangements are clearly seen in figs. 4 and 5, which are enlarged views of figs. 2 and 1 respectively.

entrance of the silt or sand into the cylinder. The tube is continued upwards to the surface of the ground, and a common suction pump is attached to it. The detail arrangements are clearly seen in figs. 4 and 5, which are enlarged views of figs. 2 and 1 respectively.

Immediately below the top or crown of the cylinder, and extending downwards a few inches, are a series of perforations, through which the water flows into the interior of the cylinder or reserve chamber. The top and bottom of the cylinder is provided with flanges ff, and the same provision is made about half way down the cylinder. The flanges sorve to support and secure the filtering medium, which consists of a sheet g of perforated metal, or gauze, which is wound round the cylinder, covering the space between the flanges. Between the perforated plates, a layer or layers of suitable material is interposed to prevent the flow or passage of the silt or sand into the cylinder, so reserve chamber, as shown in fig. 6, which are secured to the inner surface or to the outer surface of the cylinder, so as to form a space and to prevent its coming into contact with the well cylinder or reserve chamber, or the space may be wholly or partially filled with charcoal, coke, coarse gravel, or other material. The space thus formed between the two surfaces, e., the reserve cylinder and the filtering medium, allows the passage of the water upwards till it

# IMPROVED SYSTEM OF WELL-SINKING.

BY MR. J. F. BENTLEY,

before referred to. The well cylinder or reserve chamber is also provided with a tube or pipe h connected to the top, and communicating with the inside, and carried upwards to the surface of the ground and provided with a self-acting air valve. The object of this tube is to allow the air to escape out of the well cylinder when it is filling with water, and also to serve as a channel to convey water into the cylinder to act as a weight in order to facilitate the sinking.

In some cases, Mr. Bentley fits radiating or lateral tubes i i to the upper part of the cylinder, which are used as feeders to the main cylinders. These tubes are perforated and provided with an external filter medium similar to that used in the well cylinder. They are arranged in trenches dug to receive them; and may be held in position by being suspended to a cross bar of wood or iron inserted into the ground above. The tubes, when laid at a small incline towards the well, allow the water collected by them to flow into the well through openings in the top or crown, where the end of the tube is secured.

Mr. Bentley's mode of sinking cylinders or

Mr. Bentley's mode of sinking cylinders or caissons in forming foundations, piers, &c., in silt, quicksand, or similar strata, by the employment of the cone v and central tube d, is represented in fig. 3. The lower length of the cylinder or caisson k is provided with an internal flange upon which the cone is fitted, and by which it is supported. The cylinder or caisson is filled with water to weight it in order that it shall sink to the required depth in the silt. At the same time, the silt or sand is pumped up from below the conical end, and, when a sufficient depth is attained, or a firm stratum is reached, the tube is turned so as to bring its perforations within the cylinder; the water is then pumped out of the cylinder. The conical bottom can be removed, and the caisson then used for the purpose for which it has been sunk.

or passage of the silt or sand into the cylinder. The external material, which acts as a filter, is provided with a series of vertical rods or tubes, as shown in fig. 6, which are secured to the inner surface or to the outer surface of the cylinder, so as to form a space and to prevent its coming into contact with the well cylinder or reserve chamber, or the space may be wholly or partially filled with charcoal, coke, coarse gravel, or other material. The space thus formed between the two surfaces, i.e., the reserve cylinder and the filtering medium, i.e., the reserve cylinder and the filtering medium, allows the passage of the water upwards till it reaches the perforations in the top of the cylinder or caisson supon this system, the surface of the soil is dug out until a sufficiently large opening is made, as shown in the engraving, and the natural water level is reached, when the conical ond of the well cylinder or caisson is lowered down to the silt or sand, and water is each of the cylinder, and the pump set in action. The silt or sand mixed with water is pumped up to the surface of the soil is dug out until a sufficiently the surface of the soil is dug out until a sufficiently and the natural water level is reached, when the conical ond of the well cylinder or caissons upon this system, the surface of the soil is dug out until a sufficiently and the natural water level is reached, when the conical ond of the well cylinder or caisson is lowered down to the silt or sand, and water is admitted, as we have already explained. The pump tube is then screwed down below the conical ond of the well cylinder or caissons upon this system, the surface of the soil is dug out until a sufficiently and the natural water level is reached, when the conical ond of the well cylinder or caisson is lowered down to the silt or sand water is element of the soil to sand water is admitted, as we have already explained. The pump tube is then screwed down below the conical ond of the well cylinder or caissons upon this the sufface of

as the pumping is continued. When the cylinder has reached the desired depth, the pumping is discontinued. In the case of a well, the cylinder is staved or fixed in its place and is ready for use. We understand that one of these wells has been at work for the last six months at Spalding, in Lincolnshire, with great success. Mr. Samuel E. K. Capps, of 17, Westgate, Peterborough, is the sole licensee and manufacturer.

# SMELTING, CARBURIZING, AND PURIFYING IRON.

MR. ISHAM BAGGS, of High Holborn, has patented some processes by means of which the smelting, carburization, and purification of iron are greatly facilitated. In charging the furnace, the coal or coke usually thought necessary for smelting is in a great measured dispensed with, and in its place Mr. Baggs burns in the smelting furnace coal gas, hydrogen, carbonic oxide, or other combustible gas or gases, and also the vapour of petroleum, naphtha, and other hydrocarbons under pressure and in combination with a blast of hot or cold air. In the case of the inflammable hydrocarbon vapours, the same may be forced into the furnace under the pressure of their own atmospheres, or by means of mechanical appliances. The gases and vapours which are employed for the purposes of this invention may be previously mixed with the air furnished by the blast, or may be caused to meet the air in the furnace or at the tuyeres. The proportions of the mixture when a combination of gas or vapour and air is employed are subject to constant regulation by valves. One very convenient mode of obtaining combustible gases for the purposes of this invention is to generate coal gas in the usual way, and then carbonic oxide, and to blow air or carbonic oxide gas under pressure through the retort containing the iron, whether in or out of the furnace, as may be desirable, coal gas or other carbides or other materials containing carbon are blown through the furnace or brought into contact with the molten metal by blowing

For the purpose of carburizing the iron, whether in or out of the furnace, as may be desirable, coal gas or other carbides or other materials containing carbon are blown through the furnace or brought into contact with the molten metal by blowing them through it. Carbon in any suitable form or combination may also be directly introduced into the furnace for the purpose of carburization, and although generally for smelting purposes it is desirable to exclude all solid mineral fuel from the furnace as part of the charge, yet where a suspension of operations is necessary, such a charge of coal, coke, or other fuel may be introduced into the

furnace as will prevent the materials on renewal of work from falling through the crucible or any iron remaining therein or below it from being permanently solidified. When purification is required, hydrofluoric acid is blown through the molten metal on its way from the furnaces, the gases being mixed with common air or with some gaseous dilnent.

#### THE NEW ZIRCONIA LIGHT.

THREE or four months ago, the news spread in England, through the medium of the scientific newspapers, that a discovery had been made in France, which would have the effect of abolishing the limelight by substituting zirconia for the lime cylinder. The advantages were stated to be that zirconia is not eaten away by the oxyhydrogen flame, and that when not in west in the state of the property in the state of the and that when not in use, it does not absorb moisture and crumble to pieces like lime; also, that in consequence of this stability, the ordinary clockwork of oxyhydrogen lamps to turn the lime cylinder would be unnecessary with zirconia. It was further said, that the zirconia gave more light than lime under the same oxyhydrogen flame. Considerable interest in the convergence of the considerable interest. be unnecessary with zirconia. It was further said, that the zirconia gave more light than lime under the same oxylydrogen flame. Considerable interest in the new invention was, consequently, raised in this country, among the many who use the limelight, but weeks passed away without anybody being able to procure the zirconia cylinders in London. One night, however, at a soirce at King's College, the zirconia light was oxhibited burning with great steadiness and brilliancy, in the presence of Professor W. Allen Miller, F.R.S., and many others, but no accurate tests were made, and both then and afterwards, the zirconia cylinders were as unprocurable in London as ever. Three weeks since, however, one of the first zirconia lamps procurable for examination in this country reached London, and was sent by Mr. R. J. Fowler, the Parisian correspondent of the "British Journal of Photography," to Mr. John Traill Taylor, the editor of that journal, with the request that he and Mr. W. H. Harrison would test its working qualities. The lamp was the property of Messrs. Harvey, Reynolds, and Co., Leeds. Accordingly, some experiments with the lamp were tried at the workshops of Messrs. Darker Brothers, philosophical instrument manufacturers, at Lambeth.

philosophical instrument manufacturers, at Lambeth.

At present, the French company refuses to sell the zirconia cylinders without their lamp be also purchased. According to the "Engineer," this lamp made for special use with the zirconia, gives a vertimade for special use with the zirconia, gives a vertical flame, and the piece of zirconia is held in it by a little brass support. The piece of zirconia was excessively small—about as big as a pea—and here at once was a source of great loss of light, because the flame was competent to raise to whiteness several times the area presented to its action. On this account alone, the total amount of light was very much less than the same flame of are writhe lines. much less than the same flame gave with a lime cylinder, so as to put competition between the two out of the question, unless the zirconia surface be very greatly increased in size. The experimentalists then cut down a piece of lime till it equalled the zirconia in size, and the lime and zirconia were exposed in turn to the fame, the result being that the zirconia was found to emit a less white and brilliant light than the lime under the same conditions, nor did variations in distance from the nozzle of the jet alter variations in distance from the nozzle of the jet alter this result. Next, many variations in the pressure of the gases were tried, but the result was not altered. Then, substituting an English "blow-through" jet for the blow-pipe sold by the French company, the same inferiority of the light from the currents was perceptible, nor did variations of pressure affect the result. Lastly, a good orthodox oxy-hyrogen blow-pipe was tried, wherein the two gases mix thoroughly some little distance behind the nozzle, and again the results were the same. These conand again the results were the same. These con-clusions do not in any way affect the question of the permanency of zirconia under the fierce heat of the oxyhydrogen flame; but such permanency, if purchased at the expense of inferior light, is too dearly bought, and will condemn the invention. Unless the inventors are acquainted with some peculiarities of zirconia unknown to those who are versed in the use of the limelight, and can by an unknown method bring out a light from the zirconia equal to that given by lime, the zirconia light, from an economi-

given by lime, the zirconia light, from an economical point of view, is a failure.

A few other experiments were tried, showing that soft lime and hard lime have to be placed at different distances from the blow-pipe nozzle to get the maximum amount of light from each. Chemical composition even more than hardness varies the amount of whiteness of the light. Magnesia cylinders were found to take a longer time to heat to whiteness and a longer time to cool than either lime or zirconia. Quartz rapidly vitrified under the flame, and asbestos could not resist the intense heat. It requires time and repeated heatings and coolings to test the permanency of zirconia under the oxyhydrogen flame to ascertain whether it does away with the necessity for clockwork apparatus. The piece used looked at the close of the experiments none the worse for the operations it had undergone, and a native zircon crystal, which, on previous occasions, Messrs. Darker had occasionally ignited under the oxyhydrogen

blow-pine, is now as hard as ever, having shown no blow-pipe, is now as narra as ever, having shown in tendency to crumble or soften like lime beneath atmospheric influences. The heat had produced in it traces of vitrification, which could be seen only by the aid of a lens.

# Regal Intelligence.

COURT OF EXCHEQUER.

June 19. (Sittings at Nisi Prius, after Term, before the LORD CHIEF BARON and a Special Jury.)

WRIGHT V. HITCHCOCK AND ANOTHER.

Mr. Grove, Q.C., Mr. Webster, Q.C., and Mr. Aston, were counsel for the plaintiff; Mr. Manisty, Q.C., and Mr. Macroy, appeared for the defendants.

This was an action brought for the infringe ment of letters patent, dated February 19, 1862, and granted to James Wilcox, for "improvements in the manufacture of frills or ruffles, and in the machinery or apparatus employed therein." The infringement complained of consisted in the sale of frills or trimmings which the plaintiff had obtained from a manufacturer in Glasgow, named Joseph Orr, and which the plaintiff, who was assignee of the patent, alleged to have been made by machinery like that patented. The defendants contended that the invention was not new, and that the more sale of the manufactured articles was not an infringement of a patent for ma-chinery; and, further, that if the article produced was claimed that ought to have been made the subject of registration under the Designs Act.

The Lord Chief Baron reserved the questions of law for the consideration of the Court. Upon the issues of fact, as to infringement and novelty, the jury found a verdict for the plaintiff.

## Correspondence.

PISTON PACKING.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—At page 438 of your last number, under the heading "Piston Packing," Mr. G. E. Donisthorpe, of Leeds, is credited with the invention there referred to. But any one who will take the trouble to refer to my specification, No. 931, April 3, 1857, will find, even relating to piston packings, all, and more than all, that is referred to at page 438 of your last number. As to the greeve fluid or water joint, I used that to keep the joints at the axes of my atmospheric condensers airtight, with a vacuum in them equal to from 22in, to 26in. of mercury, from 1842 up to 1850. Those packing boxes were packed with unspun hemp, and they would run for two years with the hemp metal as smooth as glass, and by occasionally screwing the gland down with the thumb and finger, and this water groove was a perfectly airtight joint. On the water sinking in the can that supplied the groove, the engine driver's attention These stuffing boxes occasioned very little resistance to motion, and gave little or no trouble. From 1852 until driven from my invention in 1857, I always used what may be called the bag fluid or water pressure to keep my steam valves to the cylinder face, against a pressure of 120lb. steam; from about the same time, the non-axial rollers were ever after used by me, and the steam valves without steam boxes were thus worked in equilibrium and the compound pressure borne by frictionless rollers; and in my specification No. 931 it is seen how this bag pressure is thrown upon the bag box or, as it is there called, the pressure box, so that all the pressure is sustained by the bag box or through the frictionless rollers, and can be thrown upon the back of the valves, as by the unscrew-ing or screwing up of two bolts to the extent of half an inch the pressure is all set on the valves through the rollers, or all taken off the valves on to the box; and the pressure can thus be in-creased or diminished at pleasure, even to an ounce, by the action of these two bolts and the arrangement there seen. In conjunction with this is my mode of having cold water, where desired, though it be in free communication with steam of 400lb. pressure. This I used from 1842, in conjunction with my regulating damper. But the bag form is not essential, as I as often used india-rubber cloth as the bag.—I am Sir, yours, &c.,
THOMAS CRADDOCK.

Birmingham, June 22.

A PARLIAMENTARY return shows that the number occurred in the British merchant service during the year 1868 was 5,237. In 1867 the number was

THE Bermuds iron floating dock left the Medway on Wednesday morning for her destination in tow of the "Terrible" and several smaller steamers. She will be towed through the Channel by the "Agincourt" and the "Northumberland," and afterwards taken in tow by the "Warrior" and other steamers. other steamers.

FROM the annual account of the Mercantile Marine FROM the annual account of the Mercantile Marine Fund we learn that £359,738 was received for light dues in the year 1868. The year's expenditure for maintenance of the lighthouses of the United Kingdom, and of vessels and establishment, amounted to £305,325, and for new works and buildings, £47,063, making together £352,388.

A STRONG party of B troop, Royal Engineer Train, are at Wimbledon preparing the camping ground and rifle ranges for the ensuing volunteer gathering. Admiralty sanction has been given for a certain number of mon belonging to the various divisions of the Royal Marines to compete for the Army and Navy Challenge Cup presented by the National Rifle Association.

The terrible destructiveness of the Armstrong The terrible destructiveness of the Armstrong segment shells now in use in the British army when fired direct into columns of troops was remarkably shown in Tuesday's proceedings at the Dartmoor trials which are now exciting so much interest in military circles; the 12-pounder segment shells having in fifteen rounds planted no less than 949 hits upon the six rows of targets, representing six companies of soldiers of the line advancing in quarter-distance column to deploy.

GENERAL GILMORE has been ordered to Savannah GENERAL GILMORE has been ordered to Savannah to superintend repairs upon Fort Pulaski, which he bombarded and almost destroyed on April 10 and 11, 1862. The work was sixteen years in building; it cost about 1,000,000dols. The Savannah "News" thinks it useless to repair the fort. The missiles from the rifled cannon of Gilmore crashed through its walls, although 7½ft. thick, with almost as much ease as a rifle bullet could be shot through butter, and the rifled gun of to-day is much more powerful than those whose penetrative power created so much than those whose penetrative power created so much astonishment in 1862.

Considerable interest was excited in February CONSIDERABLE interest was excited in February last by the fact of the Cunard steamship "Russia." Captain J. Cook, and the Inman steamer "City of Paris," Captain Kennedy, both iron screw vessels of great speed, having left New York for Queenstown on the same day, and within a short time of each other, and heavy bets were made in Liverpool on the result. The "City of Paris," on that occasion, gained 42 minutes on her great rival, she having made the voyage across the Atlantic in 8 days

19 hours, 23 minutes, and the "Russia," in 8 days 20 hours, 5 minutes, the distance from New York to Queenstown being about 2,855 miles.

A BOARD OF TRADE return, probably intended to be annual, shows that the deaths of 5,237 seamen in be annual, shows that the deaths of 5,237 seamen in the British merchant service were reported to the Board of Trade in 1868, a rather smaller number than in 1867. 2,926, more than half the whole number, were drowned, 1,785 of them in wrecks; 28 committed suicide, 26 died of sourvy, 546 were carried off by fever, 175 by cholera, 216 by dysentery, 100 by diarrhesa, inflammation, &c.; 2,111 were between 20 and 30 years of age, 1,935 were able seamen. The return includes some deaths in British colonial ships; it contains, also, many, if not most, of the cases of men who die under similar circumstances in the United Kingdom.

The "Monarch" was taken into dock at Ports-

THE "Monarch" was taken into dock at Portsmouth, last Friday, for the purpose of having her hull below high-water line cleaned and recoated with an anti-fouling compound. For the purpose of with an anti-fouling compound. For the purpose of testing the qualities of various compounds, her hull was coated with them some twelve months ago, and, since that time, she has been lying in the Medway. Upon the water being pumped out, nearly the whole of her sides were found to be covered with crustaces, windled with wavely recentation. of her sides were found to be covered with crustacea, mingled with varied vegetation. A part, however, was singularly free from any such encrustation. It had been coated with a composition invented and patented by Dr. Sim, who appears to have brought his efforts in this extremely important matter to something very near perfection. We understand that the Admiralty have arranged with Dr. Sim to have the whole of the hull of the "Monarch" below high wrater line coated with his composition high-water line coated with his composition.

The Board of Trade have made the following awards:—A binocular glass to Captain J. Figaret, of the French ship "Clotilde of Cette," for having rescued the master and crew of the barque "Martha or the French snip "Clothids of Cette," for naving rescued the master and crew of the barque "Martha Kay," of Whitby, from their sinking vessel, when in latitude 29-22deg. N. and longitude 39deg. W., on July 18, 1868. A telescope to Captain John Winsor, of the brig "Magic," of St. John's, Newfoundland, for having rescued the master and crew of the brig "Othello," of Greenock, on February 4, 1869. The "Magic" fell in with the "Othello" in a disabled state on February 3, but owing to the heavy sea no assistance could be rendered till the following day, when the crew were taken on board, after being verykindly treated, and were landed at St. John's on February 28. A binocular glass to Captain T. G. Wragge, of the brig "Delphin," of Oldenburgh, for his humane services to the master and crew of the brigantine "Rosebud," of Truro, which vessel was abandoned on January 29, 1868, in the Mediterranean, in a sinking condition. The rescued crew were put on board a pilot boat off the Lizard, after having received every kindness whilst on board the "Delphin."

# Miscellanea.

A PATENT has been obtained in America for the manufacture of waterproof paper. It will be no uncommon thing, by and by, to carry a quart of milk home in a paper bag.

THE death is announced at Cheltenham of Mr. Charles Sturt, formerly of the 39th Regiment, one of the earliest explorers of the Australian continent, and subsequently Colonial Secretary of South Australia

It is believed that the statement from Honduras in the New York papers of a survey of "the Honduras Interoceanic Railroad" having been made by a Mr. Robert Fitzroy, at an estimated cost for its construction of 1,885,000dols., is entirely without foundation. The Government line is being actively considered by Massey Waring and MyCandlish carried out by Messrs. Waring and M'Candlish.

Last Friday afternoon, Mr. Layard, M.P., Mr. Cowper, M.P., Mr. Barry, Mr. Woolner, and others, made a formal inspection of the new statue of Lord Palmerston, which has been placed on the northern green plot of ground facing New Palace-yard. It has not yet been decided whether the statue shall permanently occupy its present site.

It is stated that Mr. Robert H. Sayre, Chief Engineer of the Lehigh Valley Railway, with a number of prominent iron manufacturers, are making preparations for a trip to England for the purpose of studying the process of manufacturing steel rails. They sail on June 22. On their return they will establish a manufactory of this kind at Bethlehem, the construction of which has already begun.

NEAR the ancient city of Aix, formerly the capital town of Provence, but now in the department of the Bouches du Rhone, an important agricultural meeting came off last week. The main feature of interest was the competition in ploughs and subscilers. The French makers put forth all their strength, but in both cases, after an exciting contest, they had to succumb to their English rivals, the Howards, of Bedford, who carried off both gold medals, and the money prize as well.

SINCE Monday last, the public are now admitted to the prize works of the schools of art of the United Kingdom submitted in national competition. These works contain many designs for manufactures, which producers will find it useful to consult. The works are exhibited in the galleries overlooking the Horticultural Gardens, for want of space in the South Kensington Museum.

The thirty-fourth half-yearly meeting of members of the London Association of Foremen Eugineers is appointed to take place at the City Terminus Hotel, on Saturday, the 3rd proximo. On this occasion the accounts will be audited and the election of a new committee will take place. The chair is to be taken, at 8 p.m., by Mr. J. Newton, president.

THE number of visitors to the South Kensington Museum during the week ending June 19, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 11,972; Meyrick and other galleries, 2,361; on Wednesday, Thursday and Friday (admission 6d), from 10 a.m. till 6 p.m., 2,231; Meyrick and other galleries, 197; total, 16,761. Average of corresponding week in former years, 16,912. Total from opening of Museum, 8,535.026.

A THEATRICAL and musical entertainment in aid of the funds of the Printers' Orphan Asylum will of the funds of the Printers' Orphan Asylum will take place at the Olympic Theatre to-morrow (Saturday), when Mr. Mark Lemon will represent the character of Sir John Falstaff, in selections from Shakespeare's historical play of "Henry IV.," to be followed by a miscellaneous concert, in which several talented vocalists will appear. The whole to conclude with the admired farce of "Good for Nothing;" characters by a distinguished company of amateurs, assisted by Miss Rose Garland.

THE committee for the affairs of the kingdom of Poland, presided over by Prince Gagarine, has under examination three projects emanating from Count Tolstoi, Minister for Public Instruction, relative to the transformation of the High School of Warsaw into a Russian University, to the foundation of an agricultural institute at Pulawki (New Alexandria), and to the transformation of the technical gymnasium of Lodgi into a technological institute. and to the transformation of the technical sium of Lodzi into a technological institute.

THE Tower Subway has now passed the nearest approach to the bed of the river, the top of the tunnel being 23tt. below the bed, and the engineer, Mr. Peter W. Barlow, jun., reports that, at the present rate of progress, the tunnel will reach highwater mark on the Surrey side in ten weeks. The ground, it is said, is so dry, that the New River Company's water laid on the works has to be taken from the shafts for the cement used in the tunnel. Air is supplied to the men by a steam engine at the shafts. Communication between the men at the face of the works and the top of the shafts is effected by electric telegraph. electric telegraph.

As an instance of the facilities afforded to modern journalism by steam and electricity, it is worth noting a feat performed by a provincial contemporary on the occasion of the division in the Lords on Saturday last. The "Western Mail," the new daily paper for the West of England and Wales, published a double number, with the result of the division, a leading article upon it, and a special report of the Friday night's debate—several columns long—three hours after the division in the House of Lords at Westminster in time for delivery in the West and disposal.

Amongst the various causes to which the present cold weather at Midsummer has been attributed is the fact that at this moment the disc of the sun has an unusual number of spots. The "Giornale di an unusual number of spots. The "Giornale di Roma" publishes a communication from the celebrated astronomer, Father Secchi, on this subject, in which that savant says:—"The sun is, at this moment, at a period of an unusual prevalence of spots. On the morning of the 7th, 33 principal ones were counted, disposed in seven or eight groups. Their number is rapidly approaching a maximum. The whole surface of the luminary is covered with them, and it appeared to us several times to present the aspect of a mass of white flakes on an ash-coloured ground."

With a view of deciding whether the Shropshire and South Staffordshire coalfields are connected by a third coalfield underneath the new red and permian, the South Staffordshire and East Worcestershire Institute of Mining Engineers are now completing arrangements by which all doubt about it will be set arrangements by which all doubt about it will be set at rest. Proposals are nearly concluded for putting down one or more large bore holes in the intervening country, and it is confidently expected that if the landowners and others interested in it will take it up with the same spirit as the large body of practical engineers are promulgating the scheme, at the end of this year considerable progress will have been made towards the attainment, if not the completion, of so desirable an object. There is no subject of greater commercial and social importance to the Black Country than the discovery of coal in the immense tract of country lying between the two coalfields.

# Patents for Inbentions.

#### ABRIDGED SPECIFICATIONS OF PATENTS.

CIE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

warned not to produce them without all acadowiedgement:—
BOILERS AND FURNACES—3684, 3699, 3701, 3710
BUILDINGS AND BUILDING MATERIALS—3697, 3703, 3725
CHEMISTRY AND PHOTOGRAPH—3695, 3712, 3714, 3722
CULITVATION OF THE SOIL, including agricultural implements and machines.—3688, 3698, 3705, 3706
ELECTRICAL APPARATUS—None
FIBROUS FABRIOS, including machinery for treating fibre, pulp, paper, &c.—3686, 3698, 3700, 3712, 3729
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—3707, 3716
FURNITURB AND APPAREL, including household utensils, time-keepers, jowellery, musical instruments, &c.—3690, 3696, 3726, 3730
GENERAL MACHINERY—3685, 3719
LIGHTING, HEATING, AND VENTILLATING—3698, 3715, 3718
METALS, including apparatus for their manufacture—3704

3684 H. KINSEY, Nottingham. Botters. Dated Decem-

3684 H. KINSEY, Nottingham. Botters. Dated December 3, 1868.
In constructing steam boilers, the inventor employs corrugated plates of metal, connected together in pairs, the ridges of one corrugated plate being connected to the ridges of the other corrugated plate by rivets or screw stays, so that the space between the plates may form a water space of the boiler, and the fastenings which connect the plates together must be sufficiently strong to withstand the pressure within the waterspace. The ridges of two plates may be brought into contact, but he prefers that they should be kept at a short distance from one another by distance pieces.—Patent completed.

Patent completed.

3685 W. SIMPSON and J. HUTTON, Northampton. Lubricating apparatus. Dated December 3, 1868.

This consists in applying to the inner end of the valve spindle a conical head or valve, and in forming on the inner end of the tube, through which the spindle passes, a correspondingly shaped valve seat, against which the said valve fits when the lubricator is not in action. The conical valve is applied to its spindle by cutting a screw on the latter, which passes through a female screw in the former, so as to allow of the adjustment of the said valve on its spindle, as required.—Patent abandoned.

3686 W. R. LAKE. Southampton-buildings. Kritting

former, so as to allow of the adjustment of the said valve on its spindle, as required.—Patent abandoned.

3868 W. B. LAKE, Southampton-buildings. Knitting machines. (A communication). Dated December 4, 1868. This relates to a machine in which the knitting is accomplished by the action of a series of teeth (projecting from the periphery of a rotating disc or wheel) and a reciprocating needle in combination with a looper, which takes the yarn or thread from the needle to form the stitches upon the teeth, and a stripper which removes the stitches as they are formed. The rotating plate or wheel which carries the series of teeth is fitted to turn on a stud or pin, which is fixed in the centre of a ring, forming a part of the frame of the machine. The frame is extended on one side of this ring, and is provided with a bracket and clamping screw, whereby it may be conveniently secured upon a table or other support. The disc or plate is geared in connection with a toothed pinion, which is caused to act with an intermittent motion like a ratchet wheel, by means of a rod attached to an eccentric which is carried on the main spindle.—Patent completed.

3687 W. B. LAKE, Southampton-buildings. Culting edible roots. (A communication). Dated December 4,1868.

This consists of a frame or stand, the upper part of which is encased; also of a shaft revolving in bearings in the frame. A balance wheel is attached to one end, and to the other end is attached the crank or other means for communicating power to the machine. A hollow cylinder open at one end is rigidly attached at the other end to the shaft, so as to be carried with the shaft in its revolution. The drum or shell of the cylinder is formed with three inclined slots extending from end to end, these slots inclining or curving towards the centre of the cylinder as they pass through the case or drum.—Patent completed.

3688 H. ROBINSON, Lewisham. Dressing millatone.

pass through the case or drum.—Patent completed.

3688 H. ROBINSON, Lewisham, Dressing millstone, Dated December 4, 1868.

This relates to machines for forming curved or convolute lines or cracks on the surface of millstones, and consists in causing the lines or cracks near the periphery or skirt of the millstone to be wider spart or coarser than those near the centre, so that the wear on all parts of the stone will be equal, thus obviating the existing disadvantage of the surface near the periphery of the stone wearing away before the surface near the centre thereof, by reason of the difference in the speed of the various portions of the surface.—Patent completed.

2688 S. Hussur Glescow. Purious, Dated December 4.

3689 S. HIRSCH, Glasgow. Dyeing. Dated December 4,

1868.
The mechanism or apparatus is composed of a shaft, supported horizontally in bearings, fixed in the sides of the dye boiler, and in which it is capable of being revolved. At or near the centre of the shaft a disc is carried, on either side of which sets of rectangular frames are placed. On these frames, hanks or skeins are hung in an unstretched state, the frames being less in breadth than the length of the hanks or skeins. The frames are, by preference, placed radially to the central shaft, but they may be placed obliquely thereto, and although they may be con

Digitized by GOOGLE

structed without openings in the inner part, yet it is preferred to make them with openings somewhat after the manner of a trellis, thus serving to keep the yarn in order without stretching it, by not allowing it too much play; or sets of three or more sticks may be fastened to the disc, to serve in the same manner.—Patent completed.

disc, to serve in the same manner.—Fatent completed.

3690 R. CHARLES, Birmingham. Thimbles. Dated December 4, 1868.
This consists in lining thimbles with glass, which may be effected in various ways, such as making the metal, or compound metal outer casing of the thimble a mould or matrix, and applying an internal plunger, leaving a sufficient space for the glass, the latter being in a soft state during the time it is being pressed into the interior of the metal or outer casing; or the glass lining may be on the exterior, the exact shape and dimensions of the internal form of the metal casing, the glass lining being held or retained by the outer or metal portion of the thimble, being lapped or spun over it (operations well-known) so as to retain the glass and form a bead around the open part of the thimble.—Petent abandoned.

3691 J. H. JOHNSON, Lincoln's Inn-fields. Cures of

as to retain the glass and form a bead around the open part of the thimble.—Patent abandoned.

3691 J. H. JOHNSON, Lincoln's Inn-fields. Cures of diseases. (A communication.) Dated December 4, 1868.

This relates to a peculiar mode of treating diseases, and to apparatus employed therefor, and consists essentially in enclosing the patient in a main airtight receiver, provided with a close fitting cover and removable front or shell, the joints being packed tight with india-rubber, the shell or front being further secured whon adjusted in position by any convenient fastening. If desired, glazed windows may be provided for enabling the progress of the treatment to be inspected by the medical attendant. The neck of the patient passes through a ring packed with an india-rubber cap or hood, which encloses the head, leaving the face only exposed. An air inlet valve is provided for admitting fresh air, when required, into the receiver, which is furnished with a vacuum gauge and flexible air tubes in connection with an air pump, as also with electrical wires for the application of electricity to the patient when requisite. In conjunction with this main vacuum receiver are employed other auxiliary receivers for the reception of the limbs, whilst the patient is still within the main receiver, such auxiliary receivers enabling an increased vacuum to be applied to any of the limbs, if requisite.—Patent completed.

3692 J. C. ROLLINS, Upper Thames-street. Nozzles. (A communication.) Dated December 4, 1862

requisite.—Patent completed.

3692 J. C. ROLLINS, Upper Thames-street. Nozzles. (A communication.) Dated December 4, 1868.

The nozzle is formed, by preference, of thin metal spun up into a screw, and a screw cap is applied thereto, which is made in a somewhat similar manner, but instead of leaving the bottom of the nozzle open to the can or other vessel, a piece of thin metal is fixed at the bottom thereof, which may be readily removed by a knife or other suitable means, when it is desired to pour out the contents of the can or other vessel.—Patent completed.

3693 W. G. AINSLIE East India Avenue. Draing peat.

can or other vessel.—Patent completed.

3693 W. G. Annslis, East India Avenue. Drying peat, &c. Dated December 4, 1863.

The inventor places the peat or other materials to be dried one open trays or shelves, leaving spaces all round for the passage of air, as is now commonly practised. These trays or shelves are carried by waggons or "lorries," provided with cranked axles, so as to facilitate the use of large, or comparatively large, wheels, and thereby render the traction more easy, and at the same time permit of the waggons or lorries being made to it, or nearly fit, the sectional area of the drying shed through which they have to pass.—Patent completed.

3694 M. P. W. BOULTON, Lew Park, and J. INRAY.

waggons or lorries being made to fit, or nearly fit, the sectional area of the drying shed through which they have to pass.—Patent completed.

3694 M. P. W. Boulton, Lew Park, and J. Imray, Westminster Bridge-road. Rotary propellers, &c. Dated December 4, 1868.

This relates to rotary apparatus for the propulsion of vessels, the object being to construct propellers capable of as easy revorsal as the screw or paddle, and of superior efficiency. It also relates to rotary apparatus of a similar kind for pumping or forcing liquids or aeriform fluids. One form of propeller is constructed as follows:—The inventors mount a wheel on an axis transverse to the length of the vossel. This wheel consists of a contral dilsc or cylindrical core, furnished with blades projecting from it, and works freely within a cylindrical casing. On either side of the wheel are guiding passages, two sides or boundaries of which are portions of cylinders, the outer one being a continuation of the cylindrical casing in which the wheel works, while the inner one is of the same diameter as the disc or cylindrical core of the wheel. Each of these guiding passages is open on one side to the blades of the wheel, so as to afford a free passage for the water to them, and is bounded on the opposite stire by a helicul surface. The positions of the helical guides and the width of the space between them in which the wheel wolks are so adjusted that if one of the helices were prolonged with a uniform curvature, it would join the other and form a continuous screw thread throughout. The guiding passages thus formed are united tangentially with passages directed fore and aft respectively, which open into the outer water as directly or conveniently as possible.—Patent completed.

3605 H. L. Mansden, Louth. Photographic prints. Dated December 4, 1868.

This consists of one or more receptacles or vessels for containing the toning or fixing solutions, or water or other liquid, in which the photographic prints or other articles to be prepared are immersed, and s

of water or other liquid.—Patent abandonod.

3696 J. S. CAPELLE, Paris. Perpetual calendar. Dated December 4, 1868.

In the calendars hitherto used a second readjusting knob was indispensable to bring back the date to the first day. By this method, when the date finishes, it recommences by the same knob and always by the same motion, of the cylinder and toothed gearing. This method is not only applicable to desks, but also to inkstands, bookcases, console tables, and other articles of furniture.—Patent completed.

to a great extent prevented from passing into the trap. The mud box, with which is cast a second vessel, contains the mid-feather, which constitutes the ordinary trap, and within which the inventor places a grid; upon a continuation of the mid-feather is cast a lug to which is hinged a dead plate formed in the same piece with the usual grid, and the plate rests at its inward end upon a mid-feather extending across the box. thereby forming a trap which is provided with a grid. The upper part of he box is formed with a projecting part, against which if the apparatus be applied to a street) the paving stones are set, and they are thus prevented from pressing against the end of the grid and sides of the face, and these parts may therefore be readily turned upward on their centre. The bottom of the mud box is inclined backwards.

—Patent completed.

3698 A. C. SIERBEN and J. LAMBE, Rotherhithe. and J.

3698 A. C. STERRY and J. LAMBE, Rotherhithe, and J. FORDERE, Blackheath. Purifying parafin. Dated December 4, 1868.

bor 4, 1868.

This relates to a novel mode of treating and purifying paraffin in the condition of loose crystals, the object being to expedite and economize the operations of separating the crystals from the fluid with which they may be naturally or otherwise associated, and of washing and drying the crystals. To this end, the inventors first submit the mixture of paraffin and oil to the action of a centrifugal apparatus acting on the principle of what is known as the hydro-extractor, by which means the solid paraffin is separated from the oil, the paraffin being retained within the apparatus, and the liquid or oil passing away through the pervious sides of the same in obedience to the centrifugal law.—Patent completed.

obedience to the centrifugal law.—Patent completed.
3699 J. R. SWANN, Edinburgh. Kiins. Dated December 4, 1868.
In order to obtain a more perfect combustion of fuel without smoke, and with economy of labour, movable or travelling firebars are applied to kiins. The firebars are received into a chamber at the bottom of the kiin, over which a dry limestone arch is turned through the openings or crevices in which the heat from the fire passes up into the kiin.—Patent completed.

· 3700 E. Francillon, Puteaux. Dyeing. Dated December 5, 1868.

by the frakeninon, Fucaux. Dying. Dated December 5, 1868.

Having cleansed the furs or hair thoroughly in any convenient manner from all extraneous substances which may have been used to remove the grease from the fur or hair, the inventor washes well in water rendered slightly alkalino. After having well washed in plenty of water, he drains the fur or hair and brushes it over with, or steeps it in, a solution prepared as follows:—17oz. of water is taken, and chloride of potash 4dr., chloride of ammonium 14dr., nitrate of antiline 15oz., and sulphate of copper 4dr., added to it. To give the bath a greater density, he uses tapicca as a thickening. In the case of detached fur or hair, the solution may be used as a bath, the fur or hair being steeped in it.—Patent completed.

the fur or hair being steeped in it.—Patent completed.

3701 J. A. FAWCETT, Wakefield. Supplying furnaces with jud. Dated December 5, 1868.

This relates to a patent, dated April 20, 1868, No. 1231.
The present improvements consist in the application to each of these holes of a hopper with a conical valve or stopper fixed on a spindle or rod on which may be a handle at the top for lifting same; also another conical stopper is fixed at the bottom end within the furnace, the two cones having their apexes upward, and so arranged that when the upper one is closed to the hopper the bottom one is open or not in contact therewith, but when raised, the top one is open to admit a quantity of fuel to drop under it, the bottom cone being closed, so the opening prevents the fuel passing until the valves or cones are dropped, when the quantity thus admitted below the top valve passes through the opening, the bottom cone distributing the same upon the fire of the furnace.—Patent abandoned.

3702 B. HUNT. Searle-streat. Wheels the communication of the communication.

abandoned.

3702 B. Hunt, Searle-street. Wheels. (A communication). Dated December 5, 1868.

This consists in the application of vulcanized caoutchout to the wheels of railway carriages and other articles of like description.—Patent abandoned.

This consists in the application of vulcanized caontchoud to the whoels of railway carriages and other articles of like description.—Patent abandoned.

3703 D. Thompson, Johnstone. Sawing machinery, Dated December 5, 1863.

The main framing of the machine is a table or bench of iron, cast in one piece, the circular saw, too, being arranged to work up through a slot in the top of it in the usual way. There are two pairs of vertical feed rollers, and each pair is held in an upper frame, which is movable horizontally on a lower slide, adjustable horizontally upon guides fixed to the main framing. Levers, carried on contress on the lower slides, serve to press the upper frames towards each other, so as to make the rollers grip the deal or batton passing between them. One lever acts directly against the inside of the inner flange of its upper frame, and this lover is made with a horizontal arm, to which a weight is applied. The other lever acts on its frame through a small horizontal lever to reverse its motion, and has its bottom connected by an adjustable screw rod to the bottom of the other lever, so that the one weight acts equally on both levers and ensures the holding of the deal or batten accurately in the centre. The lower slides are adjusted by horizontal screw spindles, which are geared together by equal spur wheels, so as to move the slides equally to or from the centre line. One of the spur wheels is connected to its spindle by a cone clutch, that is to say, it is formed with a conical eye to fit a conical boss on the spindle, on which it is diphtened by a two-handled screw nut, so that it can be loosened when it is wished to adjust the slides independently of each other. The spindles of the feed rollers project downwards, and have bevel wheels on their lower ends in gear with bevel wheels on their lower ends in gear with bevel wheels on their lower ends in gear mith bevel wheels on their shorts that, fitted with, affirently sliced pulleys, to receive a belt from the shaft of the circular saw.—Patent com

completed.

3697 F. Beech, Salford. Gulleys. Dated December 4, 1868.

This consists in an arrangement of gulley or stench trap, and mud box, whereby the inventor is enabled to clean the same without breaking up the street, if it be so applied, and by which the mud and other solid matter is

and resinous matters used in making sheep smear Patent completed.

Patent completed.

3705 H. DENTON, Wolverhampton. Chain harm.
Dated December 5, 1868.

Upon a pair of travelling wheels he mounts if rame and pole, or a pair of horse shafts. Upon the axle of the wheels, or upon a transverse shaft parallel with the axle, he fixes or fits a barrel or drum to rotate with the axle, to run loose upon the parallel shaft, which barrel or drum is made to revolve by a clutch coupling or gearing connecting it with one or both of the travelling wheels. A stop plate or slide is also provided for fixing the drum in position, which is formed and operates as havenafter described. To this barrel or drum one end of the chain or jointed harrow is attached, so that the whole or any portion thereof can be wound up as required.—Patent completed. completed.

portion thereof can be wound up as required.—Patent completed.

3706 E. K. DUTTON, Manchester. Gig mills. (A communication). Dated December 5, 1868.

On each side of the centre of the raising cylinder is mounted a frame, carrying at one end a leading roller, the other end swivelling around a centre or falcrum. These frames being fitted with nuts, on which work screw shafts, cut right and left hand, the arrangement being such as that the two frames may approach each other, or may recede therefrom, according as the said screw shafts are turned in one direction or the other. An intermediate leading roller is mounted in bearings capable of being moved towards or from the centre of the cylinder, and in the direction of the centre line of the said cylinder or thereabouts, each one of the said bearings being operated upon by a screw, and the two screws being connected together by a shaft, fitted with bevel wheels gearing with corresponding wheels fixed to the screws. Each of the aforesaid frames carries a set of three guide rollers, over which the cloth is passed in order to break the contact with the cylinder, two other guide rollers being employed to guide the cloth on the intermediate leading roller, each of which swivels upon a centre fixed to or carried by the contiguous swivelling frame, the other end being connected by means of a link to one of the bearings of the intermediate leading roller, so that the motion of the said guide roller is governed both by the swivelling frames and by the said intermediate leading roller,.—Patent completed.

3707 A. V. Newton, Chancery-lane. Flour. (A communication). Dated December 5, 1868.

pleted.

3707 A. V. Newton, Chancery-lane. Flour. (A communication). Dated December 5, 1868.

The object of this invention is to fit the flour asit comes from the millstones for being immediately dressed through silk. For this purpose it is necessary to extract from the flour the moisture which it contains, and at the same time to reduce the temperature of the flour to that of the air in the mill. To attain this end, a novel arrangement of apparatus is employed, in which the flour is discharged down an air channel. It is met by an upward current of air, as has heretofore been proposed, but by this apparatus the flour is effectually prevented from escaping into the mill or obstructing the escape of the air and moisture.—Patent completed.

3708 A. Masson. Edinburgh. Steam engines. Dated.

moisture.—Patent completed.

3708 A. Masson, Edinburgh. Steam engines. Dated December 5, 1868.

This relates to mechanism whereby the ordinary, or other suitable governor, is made to act on a double-beat or equilibrium valve, so as to vary the durations of the admissions of steam to the steam or valve cheat of a steam engine. The movement for opening the equilibrium valve is derived from the crank shaft, or other conveniently moving part of the engine, and is transmitted through a catch lever or intermediate piece, hereinafter termed the catch, which, whilst moving in the direction to open the valve, is also made to move laterally by the action of an incline, or its equivalent, until it escapes off the end of the bar acting on it, whereupon it allows the water to close the valve, always opening again at the commencement of the succeeding stroke. The part acting on the incline is shifted by the governor, so that the escape takes place at a later or earlier period, in accordance with the action of the governor.—Patent completed.

3709 J. Abraham, Birmingham. Central-fire cartridges.

escape takes place at a later of earlier period, in accordance with the action of the governor.—Patent completed.

3709 J. ABRAHAM, Birmingham. Central-fire cartridges. Dated December 5, 1868.

The inventor makes the chamber to receive the anvil and percussion cap of a cylindrical figure and in one piece with the head of the cartridge case, the sides of the chamber being made of a double fold of the metal of the head. A hole, of a size proper to admit the percussion cap to be used, is made in the centre of the said head. The anvil, hereinafter described, is introduced into the chamber from the open end or mouth of the cartridge case, and the chamber is closed upon and made to retain the anvil. The chamber is made by pressing or shaping by dies, and pressing a deep annular groove or depression in the flat part of the head. A portion of the metal of the head is thereby forced into the interior of the powder case, the double fold, described, of the chamber being at the same timo produced. The anvil hereinbefore referred to consists of a conical block of metal having in its axis a hole or passage, and in its base, and concentric with its deep axis, a deep groove or depression, of a size proper to receive an ordinary percussion cap.—Patent abandoned.

3710 J. HOLMES, Bradford, Kilns. Dated December 5

3710 J. HOLMES, Bradford, Kilns. Dated December 5, 1868.

The kilns are constructed as follows:—An annular smoke chamber is built around the chimney in the centre of the kiln, and communicates with the said chimney, by means of flues formed in the wall thereof. Permanent radial division walls are built in the kiln, which walls extend from the smoke chamber to the outer wall of the kiln, and divide it into firing compartments or chambers, in which the goods to be fired are placed. Flues are made in the said division walls to connect one chamber with another, and other flues are made in the wall of the smoke chamber to connect it with the firing chambers of the said flues, being closed, as required, by means of sliding dampors. Firing holes are formed in the outer wall of the kiln, and other holes (provided with covers) are formed in the top of the kiln, for the purpose of allowing steam to escape during the first stage of burning goods, and inserting fuel during the last stage of burning goods, and inserting fuel during the last stage of burning copenings or wickets (large enough to admit a horse and cart) are made in the outer wall of the kiln, one to each chamber, through which openings the goods are taken into and out of the kiln.—Patent completed

3711 B. FOWLER, D. GREIG and R. BURTON, Leeds.
Steam cultivating machinery. Dated December 5, 1868.
In order to lift the times or tilling tools of cultivating

implements out of the ground, to enable the implement to implements out of the ground, to enable the implement to turn, and also in order to turn the implement, the inventors mount upon it on an axis a lever. to which, at its free end, the hauling ropes, for drawing the implements to and fro, are attached. When the implement has arrived at the end of its course, and what was the slack rope becomes the draft rope, the first action is to cause the lever to move round, and a pulley upon its axis then winds up a chain passing to a quadrant on the axie of the carrying wheels of the implement. The axie is thus turned partly round, and being cranked at the ends where the wheels are carried by it, the wheels are thus depressed in respect to the frame of the implement, or, in other words, the frame with the tines or tilling tools is raised.—Patent completed.

3712 D. H. PATERSON Spencefield. \*\*Rianking.\*\* Dated

3712 D. H. PATERSON, Spencefield. Bleaching. Dated December 5, 1868.

3712 D. H. PATERSON, Spencefield. Bleaching. Dated December 5, 1863.

This consists in the use of one or more chest or chests made of iron or other similar material. The chest must be of sufficient strength to sustain a pressure of, at least, 10lb, weight to every square inch of its surface, and is furnished with a lid or cover, to be screwed down upon it and made steamtight by means of a gashet or other steamtight joint. The lid may be lifted off the chest by means of a travelling crane, and one lid or cover may thus be made to serve for more than one chest. The chest must be lined with lead, or other anti-corrosive material, in order to prevent any chemical action by the bleaching or dyeing solution employed upon the iron, or other material, of which the chest is constructed.—Patent completed.

3713 W. B. LAKE, Chancery-lane, Removing stem from printers' type. (A communication.) Dated December 5, 1868.

This consists of a stock or frame by which the apparatus is attached to a printers' type casting machine in such a position with reference to the mould as to catch or receive the newly cut type immediately after it is discharged from the mould. In the upper surface of the stock is formed a gutter for tho type to descend in vertically; through the gutter is cut a hole into which is fitted an adjustable plug attached to a right-angled lever working on a centre pin, which, when drawn back, lets the broken-off jet of type-metal escape while the upper sildes down the gutter to escape from the end of the apparatus. This plug is kept in its place by a spring. There is a sliding adjusting plate secured to the face of the stock by set screws, working in slots in the plate.—Patent abanby set screws working in slots in the plate.-Patent aban

by set screws working it stock that the doned.

3714 A. M. CLARK, Chancery-lane. Disinfecting sewage.
(A communication). Dated December 5, 1868.

This relates to the manufacture of double phosphate of magnesia and iron, and also to the application of the same for the treatment of sewage waters and other similar matters, and for disinfecting and enriching the residuum of said waters or matters.—Patent completed.

of said waters or matters.—Patent completed.

3715 A. B. Berre Patent Completed.

3716 A. B. Berre Patent Manufacturing gas. Dated December 5, 1868.

The coal, wood, turf, or other suitable fuel employed, is introduced through the upper opening provided with an hydraulic bell or cover into a tube widening out into a conical form at its lower part. This part is perforated with holes to facilitate the escape of gases. This tube rises or falls so as to regulate the height of the charge in the receiver of the gas generator, which is supposed to be full of fuel. The shape of the interior of the gas generator is that of two cones with their bases opposite each other, attached together by a cylindrical part. This arrangement has the advantage, when employing rich coals which expand, of facilitating the descent of the charge into the upper part of the receiver in which the coal has not been converted into coke by the volatilization or the decomposition of the tarry substances.—Patent completed.

3716 J. E. Woolf, New Bond-street, W. Cooling milk.

position of the tarry substances.—Patent completed.

3716 J. E. Woolf, New Bond-street W. Cooling milk.
(A communication). Dated December 7, 1868.

This relates to the construction, arrangement, and combination of certain concentric, cylindrical, of otherwise suitably shaped vessels, each vessel being made with double walls or sides, affording spaces between the walls or sides for the circulation and passage of the cooler fluid. Through the bottom of the vessels, and fitted with watertight joints, are short pipes, having made in them openings communicating with the said spaces, so that the cooler fluid entering the bottom of the apparatus may be made to fill and pass through all the said spaces to the points of discharge at the top of the said vessels.—Patent abandoned. points of the abandoned.

3717 W. CHISWELL, Islington. Roughing horses. Dated

December 7, 1868.

The rough or roughs consist of a three cross fron bar or bar plate in two separate pieces, with shoulders to flinside the shoe, and flat at the ends, and so arranged, by means of a serew and nut, as to take a lever bearing on the shoe itself, and not in any way press upon the sole of the foot or feet each bar or cross plate is drilled to receive one or more sharpened steel pegs or roughs, threaded to serew into the bar at given distances, so that each three-crossbar or bar plate is furnished with three or more of the steel pegs, removable as may be needed from wear or otherwise, and replaced by others, or newly sharpened.—Patent abandoned.

3718 A. Hompray, Helesower, March 1998.

Patent abandoned.

3718 A. HOMPRAY, Halesowen. Manufacture of coke.
Dated December 7, 1868.

This has for its object, principally, to make coke from small cosl or slack, but may also be applied to the manufacture of coke from lumps of cosl. The inventor takes slack, or coal broken into slack, and consolidates the said slack into blocks by driving it little by little into moulds or rings of iron fireclay, or other strong material, or into a chamber of a furnace, the slack being, by preference, wetted with water during the consolidation process. The consolidation of the slack in the moulds or rings, or chamber, is effected by the percussive or stamping machinery hereinafter described. The moulds containing the consolidated blocks are heated in a furnace, and the coal is thereby converted into coke. He prefers to pile the moulds filled with consolidated slack upon one another, so as to prevent, as far as possible, the combustion of the coal during the coking process; or the blocks of consolidated coal may be coked without being protected by their moulds or rings.—Patent completed.

3719 J. Ridley, Belsize Park. Motice power. Dated

2719 J. RIDLEY, Belsize Park. Motive power. Dated December 7, 1868.

This consists in improved apparatus for obtaining motive power from wind for pumping or other purposes. The apparatus consists of a vane or blade combined with a pendulum and other parts in such manner that the face of the vane or blade is first presented to the wind to pro-

duce the movement of the vane in one direction, and the edge of the said vane is then presented to the wind, so that little or no resistance is offered to the return movement, which is effected by a pendulum or weight attached to or rigidly suspended from the vane.—Patent completed completed.

completed.

3720 A. KRUPP, Essen, Prussis. Breech-loading ordnance.
Dated December 7, 1868.

This consists in certain mechanical arrangements for more easily and effectually manipulating the wedge used for opening and closing the breech, and also for effectually locking such wedge in its position for firing, and at the same time accurately determining that the wedge is in its proper position in the gun. Also for igniting the charge in the gun by a vent through the centre of the wedge.

—Patent completed.

3721 E. Sinova, Shaffield, Moreobert, Pated Bosen.

3721 E. SIMONS, Sheffield. Horseshoes. Dated Decem-

This consists in a light steel or wrought-iron frame pro This consists in a light steel or wrought-iron frame pro-vided with a ball plate for covering in the hollow part of the hoof, and three or more "calks" or projections be-neath for giving a firm foot hold. A toe cap projects upwards in front over the toe of the hoof, and two heel clips are provided at the rear, the said heel clips being made of spring steel, and connected together by a screwed and slightly cranked bar, by turning which they can either be separated for placing the shoe on the hoof, and removing the same or closed in for fixing the shoe firmly when required.—Patent abandoned.

3722 W. R. LAKE, Chancery-lane. Photographing by artificial light. (A communication). Dated December 7,

1863.

The interior of the room or apartment is curved above and at the front and sides of the point whereon the light is to be concentrated, and a magnesium lamp or burner is arranged in such a position that its light will be reflected upon the said point. An opening is made in the curved end of the room for the camera, and a suitable background is placed at the other end. A lamp of any ordinary kind may be used for focussing.—Patent completed.

ary kind may be used for focussing.—Fatent completed.

3723 W. R. LAKE, Chancery-lane. Railway carriage wheels. (A communication). Dated December 7, 1868.

This wheel consists of the metallic shell provided with a deep rim, which forms the tread of the wheel, and a flange by which it is kept on the rail. There is an annular shoulder and a segmental clutch. Immediately within the rim is placed a rubber ring, the thickness of which is equal to the depth of the rim and shoulder. This ring is supported from the centre by the annular metallic shoulder encompassed by the ring.—Patent completed.

2724 C. F. C. CERTIN and I. WATSON Glasgow. Sup.

shoulder encompassed by the ring.—Patent completed.

3724 C. F.C. CERTIN and J. WATSON, Glasgow. Supplying air to dirers. Dated December 7. 1868.

This consists in drawing off or exhausting the foul air and gases, thereby allowing fresh air to flow down the fresh air, as heretofore practised. This is effected by means of a fan or exhauster, which may be driven by a system of wheelwork actuated by springs or by any other convenient method. The fan box or casing is connected to the tube or tubes, which communicate with the diver's helmet and lamp, through which the foul air and products of combustion are drawn off and discharged into the atmosphere, thus producing a partial vacuum within the helmet and lamp, which may be supplied with fresh air by means of one main air tube provided with two branches at one end, one of which is attached to the diver's helmet, and the other branch to the lamp.—Patent completed.

3725 T. RENNAN, Dublin. Latches or fastenings. Dated

and the other branch to the lamp.—Patent completed.

3725 T. RENNAN, Dublin. Latches or fastenings. Dated December 7, 1868.

It is proposed to secure the wires or wire ropes to the uprights or standards of strained wire fences by the aid of metal caps, rings, staples, or straps, fitted in some cases outside the standards, and in other cases, where hollow standards are employed, inside the standards. A hole or holes is or are made horizontally through the caps, rings, staples, or straps, so as to correspond to another hole or holes made transversely through the uprights or standards for the passage of the wire or wire ropes. After introducing the wire or wire rope, and straining the same in any suitable or well-known manner, it is gripped or held securely in its place in the upright or standard by the action of one or more wedges, which cause the cap, ring or strap to move slightly in or upon the standard, and thereby nip the wire between the opposite inner surfaces of the holes, made respectively in the standard and in the cup, or other like attachment.—Patent completed.

pleted.

3726 A. M. CLARK, Chancery-lane. Thread winders. Dated December 7, 1868.

This relates to an improved mode of winding silk, cotton, jute, and other threads, cord or twist, used for sewing and other purposes, or it may be fine wire, for the purpose of retailing the same. A flat card or plate of thin wool or metal is provided on each edge, with spaces or hollows corresponding with each other, so as to produce as many divisions as there are spaces in each edge. The winder is to be made of varying thickness and dimensions, and also with a greater or less number of divisions, so long as there are two or more. The winders may also have distinguishing colours, for indicating the size and quality of the silk or other threads are to be wound on the divisions of the winder in lengths, varying according to the size. The winding may be effected either by hand or machine.—Patent completed.

3727 C. FARRAR, Bow. Reducing wood to fibres. Dated

3727 C. FARRAR, Bow. Reducing wood to fibres. Dated ecember 8, 1868.

3727 C. FARRAR, Bow. Reducing wood to fibres. Dated December 8, 1868.

The inventor mounts upon a east-iron or other frame, in suitable guides, a reciprocating plane or cutting tool. In this plane there is fitted one or a pair of plane irons with adjustable screws or wedges, and with their cutting edges upwards and facing each other, when two are used. In advance of each plane iron is a metal box let into the body of the plane, and provided with a number of sharp pointed knives or lancets, which may also be adjustable and serve to score the wood longitudinally in front of the plane iron, thereby having the effect of reducing the shavings to narrow shreds or filaments. One or a pair of feeding hoppers is mounted upon the frame, and each hopper is provided on its opposite parallel sides with roughened, fluted or toothed feeding rollers, which are carried in suitable slots in the hopper, and are kept pressed inwards by springs, so as to nip the pieces of wood which are supplied edgewise into the hopper, and gradually feed or propel them downwards on to the plane as fast as the setting proceeds.—Patent completed.

3728 A. MACHIE, Warrington. Type composing appeared December 8, 1868.

3728 A. MACHIE, Warrington. Type composing apparatus. Dated December 8, 1863.

The type pockets are stationary, and are arranged in a circle, or a portion of a circle, around or over a revolving wheel or frame, the wheel carrying a number of pick-pockets, each of which is capable of withdrawing type from one of the pockets, the precise pocket upon which each pickpocket shall operate, being in one arrangement determined by the position of the perforations in a strip of paper, acting in concert with a system of levers and triggers or fingers in manner as or nearly as follows:—

The system of perforations which is found suitable is similar to that employed in former and hereinbefore mentioned apparatus, in which each letter or sign is represented by two or more perforations, the distinctions between the several letters or signs being effected by changing the positions of the perforations from one to another of a series of straight lines, or imaginary lines, as, for example, fourteen, which number will in ordinary cases be found to be sufficient. The strip of paper thus perforated drum or plate and into contact with a series of fourteen pins, attached to or formed on a corresponding number of levers or triggers, each movement of the paper bringing two perforations opposite to two of the pins, which said two pins enter the said perforations, and the corresponding levers move into position to set one of the pickpockets.—Patent completed.

3729 H. A. BONNEVILLE, Paris. Spinning looms. Dated December 1, 1962.

3729 H. A. BONNEVILLE, Paris. Spinning looms. Dated December 8, 1868.

December 8, 1868.

This consists in a pressure piece oscillating on a pivot, which slides in a slide at the extremity of a support, fixed to the bar of the loom, this oscillation being obtained by means of a connecting or drawing rod, of which one extremity is fixed to the said pressure piece, whilst the other extremity is connected with the lever of a steelyard, the movable counterweight of which allows of increasing or diminishing the pressure exerted by the pressure piece on the rollers.—Patent abandoned.

3730 W. J. THICKENEE, Islington. Watches. Dated De-ember 8, 1863.

on the rollers.—Patent abandoned.

3730 W. J. THICKENER, Islington. Watches. Dated December 8, 1868.

This consists in introducing into the impulse lever a gold stud or screw, slotted through to receive the jewel, the points of which are curved elliptically for taking into the notch of the roller, and giving the vibratory impulse to the balance, by which arrangement greater mathematical accuracy of adjustment and perfect solidity of the working parts is maintained than by the system at present in use. In connection with the above the escapement wheel is formed with the points and stems of the teeth cut at obtuse and acute angles upon the periphery of the wheel, so as to form locking teeth, at the same time obviating banking pins, and thereby giving a double impulse action to the balance, and, in the event of the watch meeting with any jar or sudden shake, the ruby pallet or pin in the roller (on striking the points of the levery unlocks the pallets, which, on being liberated, run down the angles of the teeth of the escapement wheel and break the force of the concussion by failing softly and propolling the pin forward, whilst the main impulse power is still on, by the result of which the vibrations of the lever are brought sooner to an equilibrium without causing any disturbance or disarrangement in the time of the watch by external motion, or otherwise, the said escapement wheel being formed of gold, and the lever and roller of tempered steel, provided with ruby pallets, obviates the necessity of employing lubricating oil; and, second, the introduction of an impreved locking detent into marine and other chronometers for compensating for any interruption or stoppage to the escapement, by which uniformity of time is effectually secured; and, third, in the construction and employment of a bi-coniform spiral timing spring, for producina concentrical vibratory action and steady oscillation of the balance.—Patent completed.

### APPLICATIONS FOR LETTERS PATENT.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

Science and Art.—A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brooches, Earrings, Lockets, &c., &c., suitable for with the most beautiful designs of Bracelets, of Brooches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[ADVT.]

This book should be returned to the Library on or before the last date stamped below.

A fine of five cents a day is incurred by retaining it beyond the specified time.

Please return promptly.
